FLORIDA HEALTH CARE ATLAS

Edited by

J. Barry Mittan, M.S.P.

Comprehensive Health Planning
Office of Regulation and Health Facilities
Department of Health and Rehabilitative Services

Bob Martinez
Governor

HRS

Gregory L. Coler
Secretary

This public document was prepared at a cost of $50,170.92 or $25.09 per copy to inform legislators, state officials, state and local planners, health care providers, educators, and members of the general public about the health status of Florida's population and the supply of health manpower, facilities and services available to meet the health care needs of Florida's residents and visitors. HRS complies with the state and federal nondiscrimination policies relating to race, sex, age and handicapping condition.

Atlas Staff

Department of Health and Rehabilitative Services

Editor: J. Barry Mittan
Staff Writers: Judy Cooper, Christine Davenport, Susan Lincicome, Barry Mittan, Cherie Roberts
Graphics Production: Kim Mehok
Data Collection and Computer Support: Nancy Brilliant, Cheryl Doby, Glenn Fiske, Lynn Gillis, Michael Hudson, Angela Mitchell, David Swartz, Tom Trumbly
Clerical Support: Ruth Chasteen

Florida State University

Project Director: James R. Anderson, Jr.
Production Supervisor: Peter A. Krafft
Cartographer: Thomas J. Richard
Student Assistants: Daniel C. Endrizzi, Tracey A. He[illegible]n, James A. Reed II, Christopher D. Wilkes, Elizabeth Ann H. Wilkes
Cover Artist: Tom Wiedenhoeft

Acknowledgements

The atlas staff is indebted to the many individuals in HRS program offices, other state agencies and private organizations who assisted in data collection for this edition of the *Florida Health Care Atlas*. Among the major contributing HRS offices were the Aging and Adult Services Program Office, the Alcohol, Drug Abuse and Mental Health Program Office, the Health Care Cost Containment Board, the Medicaid Program Office, the Office of Licensure and Certification, the Office of Vital Statistics and the State Health Office. Other state agencies contributing to the atlas included the Department of Education, the Department of Highway Safety and Motor Vehicles, the Department of Insurance, the Department of Labor and Employment Security, the Department of Law Enforcement, the Department of Professional Regulation, the Executive Office of the Governor, the Florida Game and Fresh Water Fish Commission, and the Florida Highway Patrol. Additional data were obtained from the American Cancer Society, the American Diabetes Association, the American Heart Association, the American Hospital Association, the American Liver Association, the American Lung Association, End Stage Renal Disease Network 19, the Florida Association of Home Health Agencies, the Florida Hospital Association, the Florida League of Hospitals, the Florida Voluntary Health Association, the Health Care Financing Administration, the National Highway Traffic Safety Association, the National Weather Service and many individual health care providers.

Dedication

The *1989 Florida Health Care Atlas* is dedicated to the memory of Wallace H. Burgess, a caring individual whose early work in health planning fostered the establishment of Florida's local health planning system. Mr. Burgess was also a firm believer in the value of education who continually worked to increase access to education for poor and minority students. His commitment to improved quality of life for every Floridian, especially those persons in need, was reflected in his dedicated work for the Department of Health and Rehabilitative Services and his extensive volunteer work with community services.

Preface

The *1989 Florida Health Care Atlas* is the third of the series to be produced by the Department of Health and Rehabilitative Services. Data collection and analysis for each atlas is provided by the Office of Regulation and Health Facilities under its legislative mandate to establish and maintain a comprehensive statewide health care data base. Until funding is obtained for the legislatively-authorized Florida State Center for Health Statistics, the Data Analysis Unit within the Office of Comprehensive Health Planning is functioning as a de facto Center for Health Statistics. The staff within this office collects much of the data used in the atlas directly and assembles the remainder from primary sources such as the Department of Professional Regulation, the Health Care Cost Containment Board, the HRS Office of Vital Statistics and the U. S. Bureau of the Census. The Data Analysis Unit also produces the basic tabular and graphic displays used in the atlas and generates the text and initial layouts through a desktop publishing system.

Florida State University provides cartographic production, camera-ready layout and related services through the Florida Resources and Environmental Analysis Center (FREAC). FREAC staff translate the electronic layouts from HRS into individual negatives for each page, then prepare more sophisticated versions of each table, graph and map. This includes preparation of negatives for multicolor printing, development of each map and shading of the chloropeth maps used throughout the atlas based on a computer-generated list of ranges for each variable. Cartographic production and printing costs for each atlas are covered through sales of the atlas to the public by HRS.

Each *Florida Health Care Atlas* serves as a basic health care reference guide for legislators, public officials, health care providers and the public. The atlases are designed for use as a set; each atlas depicts different types of health care and health-related data based on a separate theme. The 1986 edition provides basic background data on Florida's physical characteristics, geography and population and a statewide summary of significant health data. It also includes a series of maps showing the statewide distribution of selected types of health care facilities. The basic theme for display of demographic data is a statewide overview of Florida's health.

The *1987 Florida Health Care Atlas* emphasizes district and county data. It includes health manpower, facilities, demographic and health status data for each district and county. The most unique feature of this version is the inclusion of a detailed map of each Florida county which shows the location of all types of health facilities within the county. City maps are provided for larger metropolitan areas. A listing of health facilities is also included. The demographic theme of the 1987 atlas is based on health status by age group. For each age group, the atlas covers morbidity, mortality and major risk factors.

Data prepared for inclusion in a 1988 edition of the *Florida Health Care Atlas* was used to prepare *Healthy Floridians, the Florida State Health Plan*. The main focus of the analysis was risk factors which contribute to increased possibilities of death, disease or injury. To avoid duplication, no atlas was published in 1988.

The current 1989 edition emphasizes long-term trends. Much of the demographic data is plotted on a 70-year trend line showing the changes in population, births, deaths and disease patterns since 1917. Substantial data is presented on all types of communicable and chronic diseases which affect Floridians. The atlas also includes several tables listing risk factors for communicable and chronic diseases and violence. Mapping of facility locations is not included in the 1989 atlas. Instead, data on the type, number, capacity, utilization and costs of facilities are included in tabular and graphic form. A list of Florida health care facilities with addresses and phone numbers is also included.

The *1989 Florida Health Care Atlas* is divided into several major sections, which include:

- **Population:** Long term population trends, population projections, current estimates of the population by age and race and related data.
- **Natality:** Long term trends in births and infant deaths, plus analyses of recent natality and infant mortality data.
- **Mortality:** Long term trends in death rates by major causes, changes in leading causes of death over time, life expectancy and analyses of years of potential life lost from leading causes.
- **Violence:** Discussion of violent causes of deaths and injuries focusing on long term trends in accidents, homicides and suicides.
- **Chronic Diseases:** Descriptions of chronic diseases with analyses of long term trends based on mortality data and descriptions of risk factors and high-risk groups.
- **Communicable Diseases:** Descriptions of communicable diseases with analyses of long term trends in disease incidence and descriptions of risk factors and high-risk groups.
- **Health Manpower:** Statistics on the distribution of licensed health professionals by county and district with additional analyses of age, race, sex and other characteristics based on surveys of practitioners.
- **Health Facilities Utilization:** Long term trend data on utilization of selected health care providers including hospitals, nursing homes and home health services. Data include admissions, occupancy, patient days, average length of stay and related variables.
- **Health Facilities Inventory:** Statistics on the number and capacity of facilities by county and district, detailed listings of hospital beds, and facilities reference lists including names, addresses and phone numbers.

The State of Florida

Florida is a large and diverse state, both geographically and demographically. Within the 800 miles from the Alabama border west of Pensacola to the tip of the Florida Keys, the geography changes from the rolling red clay hills of the Panhandle to the swampy Everglades and the sandy islands of the Keys. In the south, a subtropical climate fosters the growth of many species of flora which would not prosper in the colder regions of the Panhandle. Florida has over 12 million inhabitants, including many elderly residents who were attracted by the mild climate and many immigrants from Cuba, the West Indies and South America who left their homelands to escape political turmoil.

For administrative purposes, the Department of Health and Rehabilitative Services has divided the state into eleven service districts. Districts 2 and 3 are the largest in area, covering 14 and 16 counties respectively in the northern part of the state. District 10 contains only Broward County in south Florida, while Districts 5 and 11 contain only two counties. Districts 1 and 2 contain only about half a million inhabitants each, while District 11 is nearing two million.

Chloropeth maps located throughout this atlas will display a variety of county characteristics. Since these maps do not contain county names, readers should reference the following map to determine the names of specific counties shown in the following pages.

Population

Population Growth

Florida's population was just under 1 million in 1918. By 1988, the population exceeded 12.5 million and represented approximately five percent of the total United States population. Florida has experienced rapid growth throughout the twentieth century, increasing by more than two percent almost every year. Only during the Depression years (1930-34) was Florida's growth rate less than two percent per year. Conversely, the 1950s were high growth years for Florida, nearly 80 percent for the decade, as the economy prospered nationally, and people relocated to Florida because of the mild climate and many opportunities. A comparison of population data for 1910 - 1990 indicates a decennial population increase of between 20 and 80 percent for the total population. The over-65 population grew by more than 75 percent for six consecutive decades, 1910 - 1970. During the 1950s this population more than doubled, increasing 133 percent.

The Bureau of Economic and Business Research at the University of Florida does extensive research concerning population trends in the state of Florida. In 1988, they projected that Florida's population will reach 15,431,009 by the year 2000. Population projections are made using a cohort component methodology in which births, deaths, and migration are projected separately for each age-sex cohort in the population. Although historical data indicated a steady increase in Florida's population, current projections suggest a slower growth rate. Total population increase per decade now is expected to be less than 20 percent, while the elderly population increase is forecasted to be between 25 and 30 percent.

Florida Population Increase by Decade, Total and Over 65, 1910-2020

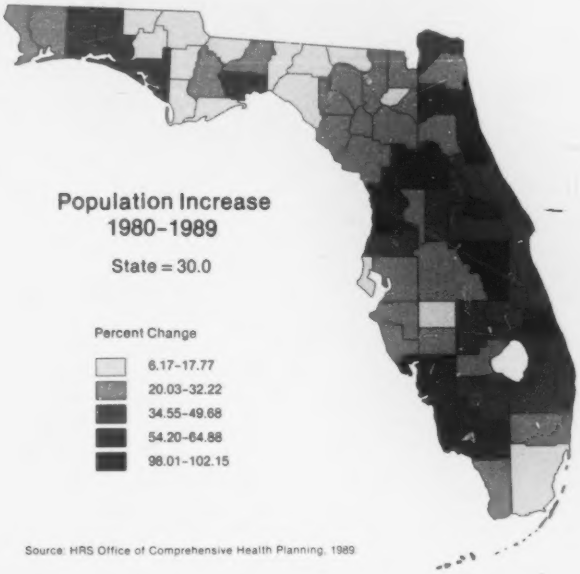
Specific population data for each Florida county indicate consistent patterns of growth. During the 1970s, population growth in Florida was rapid in those counties contiguous to urban areas. Almost all high growth counties had small populations in 1970 and are geographically adjacent to counties which had undergone high growth rates earlier and had, to some extent, become saturated. Population data for each county for 1980 to 1989 reveals many similarities to the previous decade and some new trends. Regionally, the central and southwest areas of the state had the largest number of counties with the highest rates of growth. Both regions exceeded the state growth rate of 30 percent for this period. Three counties doubled in population between 1980 and 1989: Hernando County, located to the north of the Tampa-St. Petersburg urban area; Flagler County, situated between Jacksonville and Daytona Beach; and Osceola County, south of Orlando. Charlotte and Citrus counties experienced over 60 percent growth during this period. Other counties with population growth in excess of 50 percent include Clay, Collier, Lee, Marion, Seminole, St. Johns and St. Lucie.



Source: HRS Office of Comprehensive Health Planning, 1989

Sales and Marketing Management publishes the annual Survey of Buying Power (SBP), an index which provides comprehensive population and income data for the previous year. The 1988 SBP made projections concerning the largest populations by Metropolitan Statistical Area (MSA) for 1992. The following four Florida cities were ranked among the top fifty MSAs: Tampa-St. Petersburg-Clearwater, Miami-Hialeah, Ft. Lauderdale-Hollywood-Pompano, and Orlando. Of the nation's fastest growing MSAs between 1987 and 1992, eight of the top ten are Florida cities. These include Naples (17.4 percent), Ft. Pierce (17.2 percent), Ft.Myers and Cape Coral (17.1 percent), Ocala (17.1 percent), West Palm Beach (16.8 percent), Melbourne (16.7 percent), Orlando (16.5 percent) and Ft. Walton Beach (16.2 percent). None of the negative growth markets are located in Florida.

District 11 was the most populous HRS district in Florida in 1988, with a total population of 1,922,000, and Dade County is expected to remain the most heavily populated of counties. On the other hand, projections suggest that Districts 7, 8, and 9 will each grow by more than 40 percent by 1995, the largest percent increase for the period.

In the Panhandle, District 3 is expected to have the greatest population percent increase of 38.64 percent between 1985 and 1995. District 4, which is on the eastern border of District 3, is projected to have a 31.16 percent increase for this same period.

In the population 65 and over, District 9 experienced the greatest increase, 128 percent, between 1970 and 1980. Other districts experiencing an increase of more than 85 percent for this period included Districts 3, 7, 8, and 10. Overall, the state population increase for this period was 72.9 percent. For the period 1985 to 1995, the estimated increase in the elderly population for the state is 46.0 percent. District 3 is expected to have the largest increase, 86.8 percent, followed by Districts 7, 1, 8, and 9, each with an estimated increase greater than the state as a whole. The estimated increase for the elderly population, by district, is consistent with the total population increase, with the exception of District 4, which is included among the top five districts for total population growth but not for the elderly population.

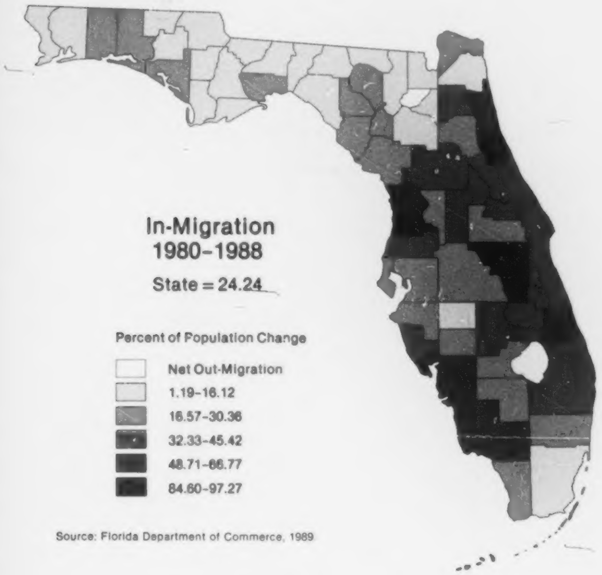
In-Migration

Population growth in a county can occur in two ways. The first is by natural increase, that is, when the number of births exceeds the number of deaths. The second is by the movement or migration of persons into a county. In-migration includes persons from outside the state, either from other states or other countries, as well as the movement of persons within the state. In-migration represented 88.47 percent of the population change from 1980 to 1988, and natural increase represented 11.53 percent.

The Bureau of Economic and Business Research has conducted several surveys to obtain economic and demographic profile data on Florida immigrants. The data presented here were collected between May 1987 and June 1988. Statewide, 4.4 percent of current residents had lived in Florida less than one year. The largest percent of immigrants, in the sample, who had lived in Florida less than one year, cited a job transfer or change as the primary reason for relocation. Other reasons frequently mentioned, by both new arrivals and persons living in Florida for a longer period of time were climate and proximity to family and friends. January was the most frequent month of arrival for immigrants; 14.6 arrived during January, according to the sample. This contrasts with February, which was the least frequent month for new arrivals. Origin data for immigrants indicate that New York sends the most immigrants, followed by foreign countries, Ohio, New Jersey, Georgia, Pennsylvania, Michigan, Illinois and Alabama. These nine areas accounted for approximately 60 percent of the immigrants during the sample period.

District 9 had the greatest population increase as a function of in-migration, 43.76 percent for the period 1980 to 1988. This reflects an absolute increase of 353,656. District 8 had the next greatest increase, 43.38 percent, followed by District 7 with 34.81 percent. The absolute increase for Districts 8 and 7 was 595,578 and 338,665, respectively. District 11 had the lowest percent increase and ranked tenth in terms of absolute growth, with an increase of 146,713.

Each of the five counties experiencing the greatest percent increase in in-migration for 1980 - 1988, had a 1980 population of less than 60,000. These include Hernando, Flagler, Osceola, Charlotte and Citrus Counties. Each county had greater than a 60.0 percent population increase due to in-migration. Only two of the counties listed above are located in one of the three districts experiencing the greatest percent increase because of in-migration. Generally, the northern part of the state, which has the lowest density, is not growing as rapidly as the central and southern portions.



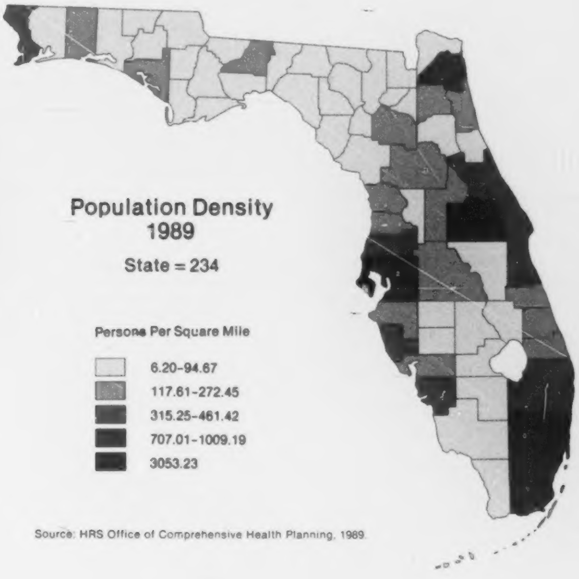
Source: Florida Department of Commerce, 1989

Population Density

Population density is the number of persons in a given geographic region divided by the land area of that region. The statistic is usually given as persons per square mile. The 1989 population density of Florida's counties varies from 6.2 persons per square mile (Liberty) to 3053 persons per square mile (Pinellas). These two counties have held the respective last and first place since 1970. The lowest densities are found in the Panhandle, beginning with Walton County in District 1 and extending to Baker County in District 3. Another cluster of low density counties is found in Central Florida, south of Lakeland, in Hardee, DeSoto, Okeechobee, Glades and Hendry Counties. The greatest densities are found in the large urban areas (Jacksonville, Orlando, Tampa, St. Petersburg, Ft. Lauderdale, and Miami). Pinellas County (St. Petersburg) is the most densely settled county because it has a large population (850,000) and a small land area (280 square miles). The 1989 average for the state was 234 persons per square mile.

Changes in the ranking of these counties relative to density has followed the overall population growth pattern. For example, in 1970 Seminole County was ranked eighth in terms of density with 281 persons per square mile. In 1989, it is ranked fourth with 903 persons per square mile. Seminole County is contiguous to Orange County, which is currently ranked seventh in terms of density. Hernando County is another example of the growth in population and increased density. In 1970, it was ranked the 35th most densely populated county with 36 persons per square mile. It is now ranked 20th with 188 persons per square mile.

Elderly population density is greatest in the southern portion of the state. Pinellas County has approximately 850 persons over 65 per square mile. Palm Beach has 110 per square mile, and Hernando has 75.12 elderly persons per square mile. Three counties in the northern part of the state - Escambia, Leon and Flagler - all report densities of elderly persons below 55 per square mile.



Source: HRS Office of Comprehensive Health Planning, 1989

Age, Race and Ethnicity

Age cohort data for the state of Florida indicates that 14.7 percent of the total population is over the age of 70. Data also suggests that the majority of the white population, 62.37, is over 30 years of age, while the majority of the black population, 57.0 percent, is under 30 years of age.

Florida has a large elderly population because of both natives of Florida as well as recent in-migrants. Data concerning in-migration indicates that 7.62 percent of all new arrivals (i.e., in Florida less than one year) were over the age of 65. Over half of the new arrivals, 54.8 percent, are under 35 years old. Therefore, many of the persons over age 65 have lived in Florida more than ten years.

Birth rates have been increasing since 1977, particularly among the nonwhite population, which partially accounts for the large percentage of persons under the age of 30. As members of the "baby boomer" population born in the late 1940s and early 1950s have reached childbearing age, the total number of births per year has increased.

The nonwhite population of the state, which represents 14.98 percent of the total population, tends to cluster in the smaller farming communities, particularly along the northern border. In four of these counties (i.e., Gadsden, Hamilton, Jefferson and Madison) nonwhites constitute more than 35 percent of the total population.

Dade County also has a relatively high percentage of black residents. This includes many black immigrants from Haiti and other Caribbean countries. However, the relatively large black population is overshadowed by the tremendous influx of Cubans and other Hispanics over the past 25 years. These Hispanic immigrants have remained concentrated in the Miami/Dade County area and adjacent counties.

Migrant and Seasonal Workers

Migrant, or seasonal, farmworkers form a group with special health service needs because of their low incomes and the hazards of their workplace. According to the May 1989 In-Season Farm Labor Report, released by the Bureau of Agricultural Programs, there were 70,522 seasonal workers in Florida between March 15 and April 15, 1989. Approximately 75.0 percent of the workers were local migrants, 14.0 percent were intrastate migrant workers, and 11.0 percent were interstate migrant workers.

The South Florida region reported a total of 35,874 workers. Approximately 68.0 percent of the workers were local, 17.0 percent were interstate, and 15.0 percent were intrastate migrants. Approximately 72.0 percent of the South Florida seasonal workers were Hispanics, 13.0 percent were nonwhite Hispanics, 12.0 percent were black, and 11.0 percent were Haitians. The South Florida area reported a 20.0 percent increase in the number of seasonal workers for the same period last year.

The Central Florida region reported 33,234 seasonal workers. A larger group of Central Florida workers, 81.0 percent, are local migrants, followed by intrastate workers, 13.0 percent; and interstate migrants, 6.0 percent.

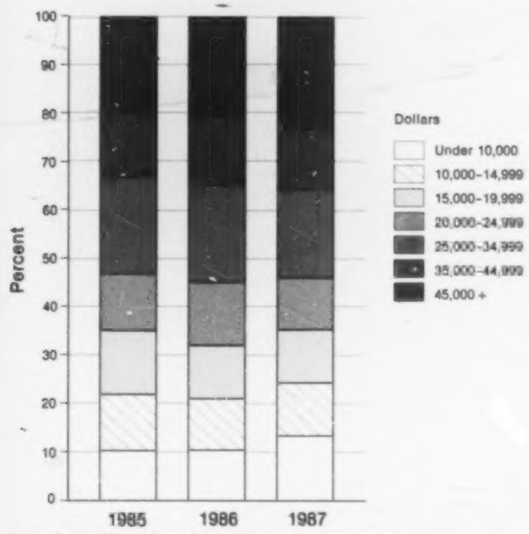
The fewest number of migrant workers, 1,414, were reported in the North Florida region. The workers are almost exclusively from the local area, 98 0 percent, with 2.0 percent from other cities and towns in Florida. This area reports a 10.0 percent decline in the number of workers for the same period last year.

Income and Unemployment

The distribution of median family income in Florida is highly skewed geographically due, in part, to the large retired population, which has a substantial nonwage income from interest, rents, and dividends, especially in South Florida, which attracts many affluent retirees.

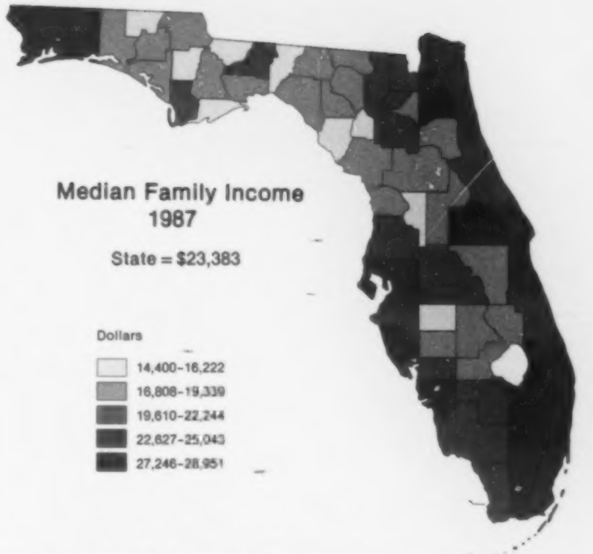
The University of Florida Bureau of Economic and Business Research conducts research to obtain income frequency distributions in Florida households. According to their most recent sample survey, income data for 1985, 1986, and 1987 indicated that the majority of households for each of the three years made more than $25,000. In 1987, 12.5 percent of the sample made less than $10,000, up from 10.1 percent in 1985. The percent of persons making between $10,000 and $25,000 per year has steadily declined since 1985. The data indicate that 36.9 percent of survey participants made less than $25,000 in 1985, dropping to 34.5 percent in 1986 and then to 33.2 percent in 1987.

Annual Family Income, 1985-1987



Source: Survey of Buying Power, Sales and Marketing Management, 1988

Based on the Survey of Buying Power, the national median household income was $25,888 in 1987. The state's median household income for Florida was $23,383, or 35th in the country. Nationally, 17.5 percent of all households made less than $10,000 in 1987; 21.3 percent earned between $10,000 and $19,999; 25.0 percent earned between $20,000 and $34,999; 17.2 percent earned between $35,000 and $49,999; and 18.1 percent earned more than $50,000. The majority of households, 61.2 percent, earned more than $20,000 during 1987. The West Palm Beach-Delray-Boca Raton MSA is the only MSA in Florida ranked among the top 100 cities with the highest median household incomes. It was ranked 77th in 1987 with a median household income of $28,555. Median household income for all Florida counties ranged between $14,400 and $28,950. Hardee County reported the lowest household income, while Clay County reported the highest.



Source: Survey of Buying Power, Sales and Marketing Management, 1988

Median family household income in 50.8 percent of Florida counties was between $15,000 and $19,999 in 1987. The next largest group, 38.8 percent, indicated a median household income of between $20,000 and $24,999. Approximately 2.9 percent of all counties reported a household income of between $10,000 and $14,999, and 7.5 percent earned more than $25,000. Median family income was generally highest in northeast and southern Florida.

The 1988 average annual unemployment rate for the state was 5 percent. The average rate for 1988 for all Florida counties ranged from 2.6 percent in Monroe County to 11.7 percent in Hendry County. Approximately 34.0 percent of all counties had an annual average rate lower than the state average. Five of the top ten counties reporting the highest unemployment rates are in the Panhandle. The remaining five are in Central Florida, including Okeechobee, Glades and Hendry Counties, which are contiguous.

Natality

Historical and Total Births

In the last century, the birth rate in Florida has changed dramatically. Although natality or birth data have been collected in Florida since 1917, some variables, such as low birth weight and neonatal mortality have been maintained for shorter periods. Statisticians use the following definition for birth rate: the number of live births in a given year, divided by the mid-year population, and then multiplied by 1,000. When calculating the birth rate by race, this atlas uses the major classifications of white and nonwhite. These categories, however, have not been defined in the same way from the beginning of record keeping. For example, historically, Hispanics were counted as nonwhite, but now they are considered white if no additional information is given. The nonwhite category also includes black Americans, Orientals, American Indians, and Pacific Islanders. Obviously the changes in definition may influence the birth rate data.

Birth rates in Florida since 1917 have fluctuated considerably, especially with regard to race. Between 1917 and 1944, birth rates fluctuated between 16 and 28 per 1,000. The white and nonwhite rates were ~~not~~ appreciably different and in fact crossed each other several times. Overall the number of white births maintained a steady rate from 1944 to 1960, but then began a decline which continued until 1980. The birth rate among the nonwhite population follows the same trend, but has been higher than the white birth rate since 1928 and is currently double that of the white population.

Varied and numerous explanations exist for the changes and trends in the historical natality data. First, from 1920 to 1925, Florida thrived economically. The birth rates among both the white and the nonwhite populations

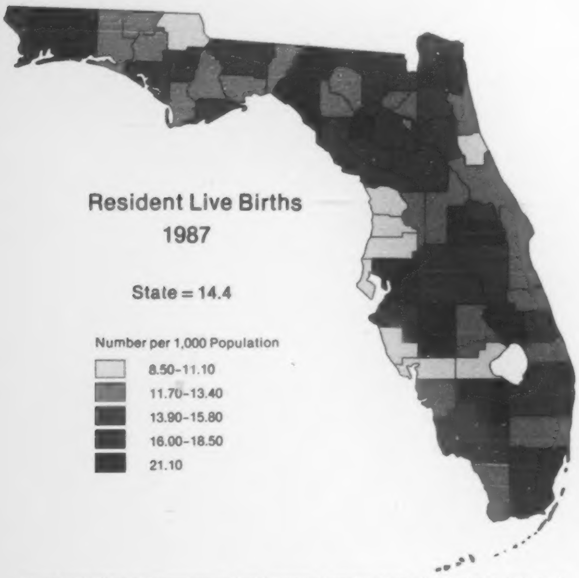
remained stable or increased during this period. However, in the late 1920s, the economic climate changed abruptly, and the change in both the financial and real estate market is reflected in suppressed birth rates during most of the Depression years. Then by the mid 1930s, Florida began its economic recovery. This trend remained until 1940, when a more significant increase in both the white and nonwhite rates is observed during World War II. Between 1947 and 1957 birth rates rose, and a period of economic prosperity between 1950 and 1957 only served to bolster the rates. The relationship between events is most clearly evident among the birth rates of the nonwhite population between 1944 and 1956, when they reached the highest point of 37 per 1,000 in 1956. Although the white population was affected by the same events, it is not so readily apparent in the resulting birth rates for Florida. The immigration of older white adults who were past their childbearing years increased the denominator of the white childbirth rates during this period, lowering the rates by migration factors.



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1917-1987.

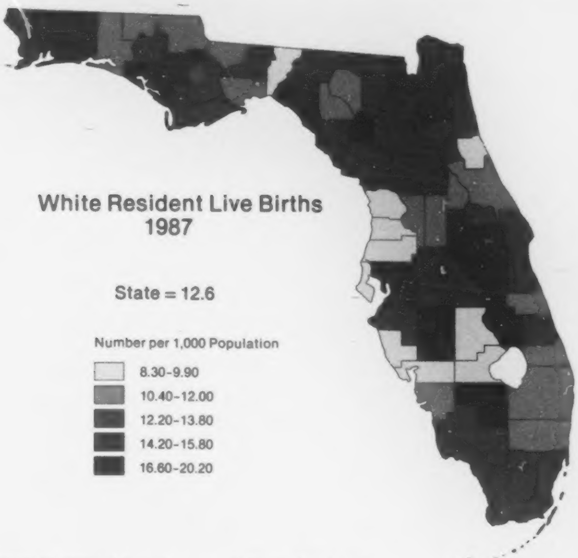
Between 1958 and 1976 both the white and the nonwhite birth rates declined, with the white birth rate reaching its lowest point of 10.36 per 1,000 in 1976. The country experienced a tremendous amount of political and social turmoil during this time which may have affected birth rates.

Since 1976, persons born during the post World War II increase have entered the childbearing ages. As a result of the larger number of persons in this age group, the birth rates have risen significantly. The absolute number of births has also risen sharply, especially the number of white births, for the increase in the birth rate is more prominent among the white population whose birth rate was 12.60 per 1,000 in 1987, the highest since 1971; but this trend is also evident among the nonwhite population with a 1987 rate of 24.70 per 1,000, also the highest since 1971.

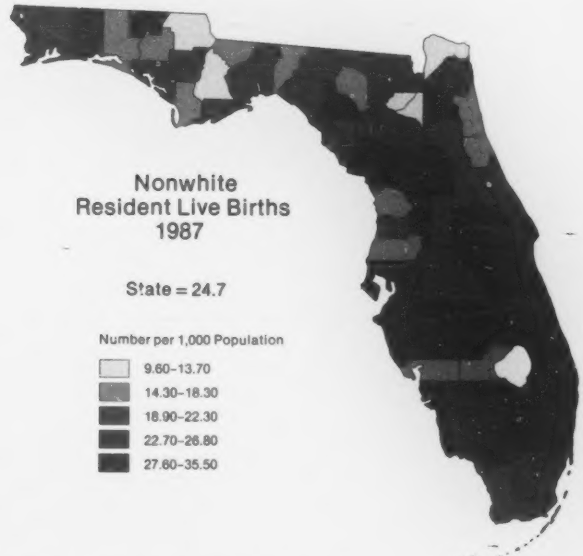
The number of resident live births per 1,000 persons has been calculated for each Florida county for 1987 by dividing the number of resident live births by the county population and multiplying the result by 1,000. The result for each county is the crude birth rate, the simplest and most common measure of natality. In the computation of this rate, all ages and both sexes are represented, so it provides a rough approximation of fertility and natality trends. Although the crude birth rate is only an approximation, it is important for comparative purposes due to its widespread acceptance and use. The crude birth rate can be based on either resident or recorded births. The births presented are resident as opposed to recorded births. That is, a birth may have occurred in a county where the mother does not reside, but, regardless, it will be classified according to the mother's county of residence.

Individual county birth rates for 1987 vary significantly from the state average. For the total population, the birth rates ranged from 8.5 in Charlotte County to 21.1 births per 1000 population in Hendry County. The state birth rate for 1987 was 14.4 births per 1000 population. This is .11 percent less than the 1985 state rate. Thirty-eight, or 57 percent, of the counties are below the state rate. The counties which have a birth rate higher than the state rate do not appear to be geographically or demographically homogeneous. They are dispersed throughout the state and include both rural and urban counties.

The white and nonwhite birth rates for 1987 differ greatly. For example, the rate for the white population ranged from 8.3 in Charlotte County to 20.2 births per 1000 population in Hendry County. The state birth rate for the white population was 12.6 in 1987, slightly below the state rate for the total population. This rate is .1 percent higher than the average rate for 1984 to 1986, which was 12.5 births per 1000 population. The five counties reporting the lowest birth rates, all below 10.0 births per 1000 population are Charlotte, Sarasota, Glades, Citrus and Hernando. These counties have a significant elderly population, which may account for the low birth rates. The five counties reporting the highest birth rates, all above 15.0 births per 1000 population, include Santa Rosa, Duval, Gilchrist, Okeechobee and Hendry, all of which are primarily rural except Duval.



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1917-1987



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1917-1987

The birth rates for the nonwhite population are much higher than the rates for the white population. For example, the 1987 state birth rate for the nonwhite population was 24.7 births per 1000 population, almost double the white rate. The five counties reporting the lowest rates, all below 14.0 births per 1000 persons, include Union, Liberty, Jackson, Bradford and Nassau, all in rural northern Florida. The five counties reporting the highest rates, all above 29.5 births per 1000 population, include Clay, Lee, Broward, Levy and Martin Counties.

For future generations to be at least as large as the present generation, that is, for birth rates to be at a replacement level, women would need to have an average of 2.12 children each. Estimating the annual replacement level for the entire population, approximately 15.14 births per 1,000 persons are necessary to achieve replacement. Birth rates of 45 Florida counties are below those needed for replacement. An increase in the population of these counties is not attributable to natural increase, but rather to other demographic factors, such as in-migration.

Maternal Age

Age cohort data for the period 1960 to 1987 indicates a gradual shift in the age when women are having children. Although the total number of births has fluctuated over this period, there has been a constant increase in the total number of births since 1977. Women between the ages of 20 and 29 have had the largest percent of births since 1960. More detailed segmentation of the 20 to 29 age cohort (20-24 and 25-29) indicates a greater percent of women in the late twenties having children than in the early twenties. This shift is observed for the first time in 1986, and is consistent with the overall aging of the population and the trend in delaying childbirth. Through 1963, women between the ages of 30 and 39 had a larger percent of children than those in the under 19 cohort. Since 1966, the under-19 cohort has represented the next greatest percent of women having children. The percent of women over 40 having children is less than 2.0 percent throughout the 27-year period. The percent is greatest in 1966 and then declines until 1981. A 23.0 percent increase in the number of births for the period 1981 to 1983 is observed in the over-40 age cohort. In 1987, approximately one percent of all births were to women over 40 years old.

Comparative data for 1959 and 1987 reveal significant differences in the age of women having children, depending upon race. The 1959 data reveal that there were more births, as a percent of total births, to nonwhite females under 19 than there were to white females in this same cohort. The percentage of births to teenage mothers has declined among the white population, but has increased slightly among the nonwhite population since 1959. For both populations, the largest percent of births, in 1959, were to women in the 20 to 24 age cohort. In 1987, the greatest percent of births in the white population were to

women between 25 and 29 years of age. The second largest cohort, among the white population, is women between 20 and 24 years of age, with a 25.0 percent increase in the 30 to 34 age group since 1957. The largest percent of births in the nonwhite population are still to women between 20 and 24 years of age, with the next greatest percent of births to females under 19 years old.

Delayed childbirth generally results in smaller families and more favorable spacing of pregnancies. Total birth rates also decline because of decreasing fertility with age, increasing perinatal mortality with age of mother, and the possibility of divorce, separation, or death. The health effects to the infant of delayed births may not be favorable once the mother reaches a certain age. The lowest neonatal mortality rate for first births is for mother's aged 20-24, and it rises steadily thereafter. Due to increased medical technology, the neonatal rate has declined significantly over the past 50 years. The current rate is 6.67 deaths per 1000 population. The fetal death ratio (rate of fetal deaths per 1000 live births) reaches a low when the mother is about age 25 and rises thereafter. The ratio at age 35 and above is almost double that at ages 20-24. The fetal ratio is slightly higher at 9.2 deaths per 1000 live births. Doubling the fetal death ratio only increases the risk to an individual mother by about one percent. Generally, the health status of the mother prior to and during pregnancy is of much greater importance than age in determining fetal outcomes. Expectant women over age 35 should consider having genetic counseling for Down's syndrome, more frequent diabetes screening, and carefully follow their physician's advice.

Teen Pregnancy

Teenage pregnancy has become more prevalent in both Florida and the United States. Births to mothers under 20 years of age are presented in this instance as the ratio of teen births per 1000 total live births.

Nearly one-eighth of all U.S. births are to teens. The U.S. teen pregnancy rate (96 per 1000) is higher than the majority of other industrialized countries. It is more than twice that of Canada (44), three times higher than the Soviet Union, and 18 times higher than Japan.

The number of sexually active teenagers is increasing in the U.S. Nationally, fifty percent of teen males and 33 percent of teen females have intercourse before age 17. Further, between 1971 and 1982, the sexual activity rate for black female teenagers increased by only 1.0 percent, while that for white female teenagers increased by 73.7 percent. Yet black teens are 250 percent more likely to become pregnant, 350 percent more likely to give birth, and 550 percent more likely to give birth as a single parent.

Teenagers who have a baby are less likely to complete high school and teens who drop out of school are more likely to become pregnant. Marital status also affects the amount of education a teen age mother will receive. In 1981, the proportion of mothers with high school diplomas was greater for married teen mothers than for single teen mothers. Teenagers often lack the financial resources and support systems to deal effectively with a pregnancy. Education may also provide some of the fundamental skills necessary to insure a mother and child's economic security. Nationally, the probability that a teenager will have another baby within one year is much higher than for older women. Twenty-five percent of pregnant teens will be pregnant again within a year, and fifty percent of teen mothers will have another baby in two years, while still in their teens (HRS Developmental Disabilities Planning Council, 1987).

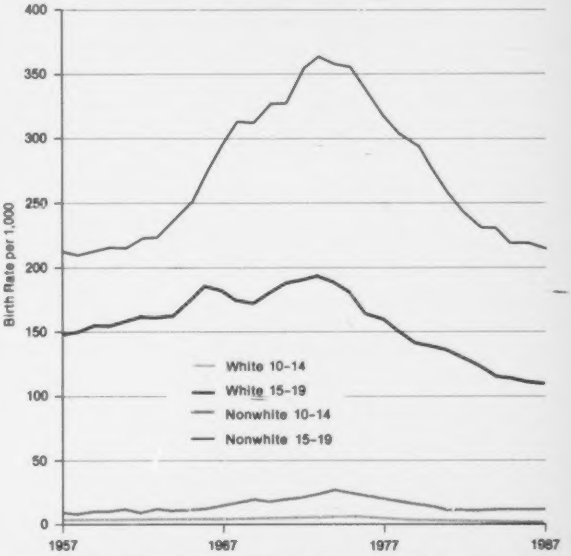
The rate of teenage pregnancies, per 1000 live births, among the white and nonwhite populations fluctuated between 1957 and 1987. The rates have been calculated for both the 10 to 14 and 15 to 19 year old age cohorts. In both age groups, the nonwhite population had a higher birth rate for each of the 30 years than did the white population.

The birth rate for the white population, age 10 to 14, ranged between .73 and 3.13 per 1000 live births from 1957 to 1987. The highest rate, 3.13, was reached in 1975 and has since declined to a 1987 rate of 1.30 births per 1000 live births. This same trend is true among the nonwhite population, although the highest rate, 21.07, is observed in 1974. The lowest rate for the nonwhite 10 to 14 age group was in 1958, when it was 8.16 per 1000 live births. The decline in the rate of births in this age cohort over the past ten years is attributed primarily to increased education and awareness concerning birth control and pregnancy.

The birth rates for teenagers in the 15 to 19 year old cohort are considerably higher than the 10 to 14 year old group. The rates for the white population ranged between 104.12 in 1987 to 196.06 per 1000 live births in 1973. The birth rates for the nonwhite population in this age group were higher than the white population's, ranging between 208.10 in 1958 and 362.66 per 1000 live births in 1973.

The range in birth rates as a percentage of total births among white females under 19 years of age in Florida counties for 1987 is 2.86 to 25.0 percent. There are 27 counties in which more than 10.0 percent of the births were to mothers under 19 years old. Many of these counties are rural and have concentrations of individuals with incomes below the poverty level. The highest percentage was in Hamilton County with 25.0 percent of all births to women under 19 years old. Six counties (Flagler, Broward, Dade, Alachua, Monroe and Palm Beach) report less than five percent of all births to females less than 19 years old.

Resident Live Birth Rates for Teenage Mothers by Race, 1957-1987



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1957-1987.

The birth data for the nonwhite population indicates a range of between 6.25 and 66.67 percent of total births to mothers younger than 19 years old. Gilchrist County did not report a single nonwhite birth in this category. Only five of the 67 counties report less than a 10.0 percent rate for nonwhite females under 20 years old. Liberty County reports the highest percentage of females less than 19 years old giving birth during 1987 at 66.67 percent.

Births to females under age 15 may be associated with problematic or fatal birth outcomes, especially premature births of low-birth weight infants due in large part to improper prenatal care. Many teen mothers do not receive prenatal care due to lack of information or inadequate financial resources. Poor pregnancy outcome is inversely related to mother's age (up to age 37). Babies born to mothers younger than 15 years old are twice as likely to have a low birth weight baby than those born to mothers 20-24 years old. Nationally only 54 percent of all teen mothers seek prenatal care in the first trimester; for black teens this drops to 47 percent. Twelve percent of mothers younger than age 20 receive no prenatal care until their seventh month of pregnancy.

Of women receiving prenatal care in the first trimester, two percent have low birth weight infants. This increases to nine percent for those women who do not have early intervention. National statistics for 1980-1985 indicate that the percentage of women receiving first trimester care nationally was fairly constant at 77 percent. Florida's 1987 statistics indicate a slight increase in the percentage of women receiving first trimester prenatal care from 67.5 to 67.8 percent, and a decline in the number of women receiving late or no prenatal care, to 3.3 percent.

Unwed Mothers

Unwed mothers represent another unique maternal group due to their special financial, educational and health care needs. A birth to an unwed mother can have many negative consequences. One is the interruption of educational opportunities if the mother is less than 18 years of age. Another possible consequence is the increased likelihood of complications at birth. Unwed mothers often feel ambivalent toward their pregnancies and thus tend to delay prenatal care. In addition, many unwed mothers are unable to pay for the prenatal care which is essential for them to have healthy babies.

Live births to unmarried women have been calculated as a percent of all live births for both state and county statistics. Historical data for Florida, for the period 1917 to 1987, show a constant increase in the percent of live births to unwed mothers. The rate of births to white unwed mothers remained relatively low, less than 2.5 percent of all live births, until 1957. Between 1957 and 1967, the percent of unwed mothers increased by more than 150 percent. Currently, 16.28 percent of all white births are to unwed mothers. Nonwhite live birth rates for unwed mothers are much higher than white birth rates. The largest percent increase in births to unwed mothers in the nonwhite population occurred between 1967 and 1977, when a 62.0 percent increase is noted. The majority, 61.3 percent, of all nonwhite births in 1987 were to unwed mothers.

Age cohort data for unwed mothers is available for the period 1960 to 1987. For each of the four age cohorts (10-19, 20-29, 30-39, over 40) a constant increase in the percent of births to unwed mothers is noted for the 27-year period. The largest percent of births to unwed mothers has always been to females in the 10 to 19 year old cohort. This is followed almost equally by females in the 20 to 29 and over 40 age cohorts. The fewest births to unwed mothers have always been to females between 30 and 39 years old. The greatest fluctuation in rates is noted in the over 40 age cohort data. The largest annual increase (46.8 percent) is noted in 1977 for the over 40 age cohort. The other age cohorts have experienced more gradual increases. In 1987, 65.67 percent of all births to people 10 to 19 years old were to unwed mothers.

The range of white births to unwed mothers in Florida counties, as a percent of total births, is 1.66 to 75.41 percent. Leon County reports the lowest percent of births to unwed mothers, and Dixie County reports the highest percent. The other four counties reporting the lowest rates of births to unwed mothers include Jackson, Dade, Broward and Flagler. All of these counties report less than 3.0 percent of all births to unwed mothers.

The percent range of nonwhite births to unwed mothers for each county in Florida is 10.0 to 68.0 percent. Although the percent range is similar to the white population, a greater number of counties report higher nonwhite birth rates to unwed mothers. Fifty of the 67 counties report birth rates of greater than 20.0 percent to unwed mothers in the nonwhite population versus seven of the counties for the white population. Gilchrist County reports the lowest rate at 10.0 percent. This is followed by Okaloosa, Charlotte, Monroe and Hardee Counties. Hamilton, Dixie, Holmes, Liberty and Flagler Counties report the highest rates of nonwhite births to unwed mothers. Each of these counties has greater than 38.0 percent of all births to unwed mothers.

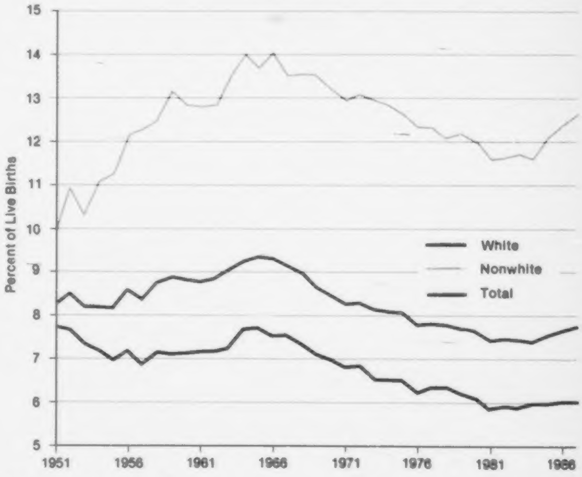
Low Weight Births

Births below 2,500 grams (about 5.5 pounds) are termed low weight births. Low birth weight is the leading cause of infant mortality. In fact, low birth weight neonates are 40 times more likely to die in the first month of life than normal birth weight neonates. For every low birth weight infant the likelihood of death is nearly 200 times greater than for a regular weight birth. Many newborns weighing less than 1,000 grams die and low birth weight infants account for two-thirds of neonatal deaths. Medical factors that increase the risk of low birth weight include multiple pregnancy, poor weight gain, a short interpregnancy interval, hypertension caused by the pregnancy, anemia and fetal anomalies. Other risk factors include age (under 18 and over 35), low socioeconomic status, race (black babies are at higher risk than other racial group), single status, and inadequate prenatal care.

Historical data for Florida also suggest a significant relationship between race and low birth weight. The data show low birth weight newborns as a percentage of all births for the period 1951 to 1987. The percentage of low birth weight babies is highest among the nonwhite population. The current rate for the nonwhite population is more than double that of the white population.

The highest rate for the nonwhite population was in 1966, when it reached 14.01 percent of all births, 7.70 percent for the white population in 1965 and 9.97 percent for the total population in 1965. Despite advances in medical technology and prenatal care, the percent of low weight births remains high, especially for the nonwhite population.

Percent of Resident Live Births Under 2,500 Grams 1951-1987



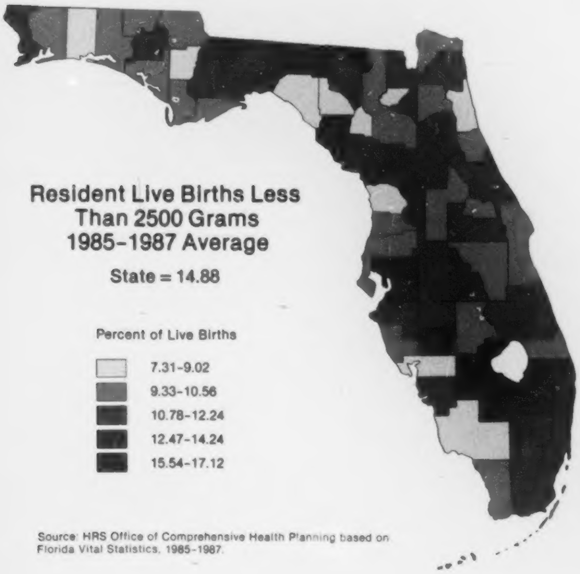
Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1951-1987.

The rate of low weight births, as a percent of total births, for each county in Florida was averaged for the period 1985 to 1987. Statistics for 1987 alone, tend to be skewed due to the relatively small absolute population and small number of births in many counties. The rates ranged from 9.31 percent in Union County to 22.32 percent in Glades County. Other counties reporting low birth weight percentages below 11.5 percent of total births include Calhoun, Okaloosa, Gilchrist and Lafayette. Each of these is a rural county. Those reporting the highest percent of low weight births are also predominantly rural and include Gadsden, DeSoto, Jefferson and Hamilton. Over 17.5 percent of all births in these counties were low weight births.

Data for individual counties concerning low birth weight infants, for 1987, varies for each sex and race. The percent range among low weight white male births is 1.79 to 8.62 as a percent of all births for each county. Gilchrist, Union, Highlands, Desoto and Jefferson Counties report the lowest percent of white male low weight births. Each of these counties has a rate of less than 3.5 percent low weight births to total births. Hamilton, Walton, Glades, Suwannee and Citrus Counties report the largest percent of low weight births.

The range of low weight white female births as a percent of total births, for 1987, is 0 to 16.67 percent. Liberty, Columbia, Madison, Lafayette and Union all report a rate of less than 4.5 percent. Washington, Hardee, Calhoun, Dixie, and Glades Counties report greater than 9.0 percent of all white female births as low weight births.

The range of low weight nonwhite male births is 0 to 35.42 percent. Six of the counties did not report any low weight nonwhite male births. These include Union, Walton, Holmes and Glades. Wakulla, Hardee, Liberty, Lafayette, and Desoto have the greatest percent of nonwhite low weight male babies, with greater than 24.0 percent of all births reported as low weight births.



Resident Live Births Less Than 2500 Grams 1985-1987 Average

State = 14.88

Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1985-1987.

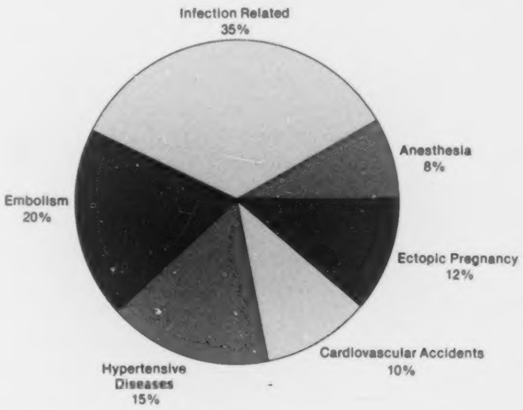
The percent range of nonwhite female low weight births is 0 to 27.27 percent. Three counties report no low weight births, and Washington, Charlotte, Union and Sumter report less than 6.0 percent of total births as low weight births. Walton, Calhoun, Highlands, Lafayette and Citrus Counties report the highest rates of low weight births. Each reports greater than 20.0 percent of total births as low weight births.

The counties reporting the highest and lowest percents of low weight births, for 1987, are almost all rural counties. The small absolute number of total births makes the percent extremely high even if the absolute number of low weight births is low. The counties in which low birth weight babies are the most common (Walton, Lafayette, Calhoun, Hardee) include low income areas.

Maternal and Infant Mortality

Maternal mortality is the death of a woman from any cause during pregnancy or within 42 days of the termination of pregnancy. A 1988 study revealed that 20 percent of maternal deaths were the result of an embolism, 15 percent were attributed to hypertensive disease, 12 percent due to an ectopic pregnancy, 10 percent related to a stroke and 8 percent due to anesthesia. Thirty-five percent of maternal deaths were indirectly related to an infection.

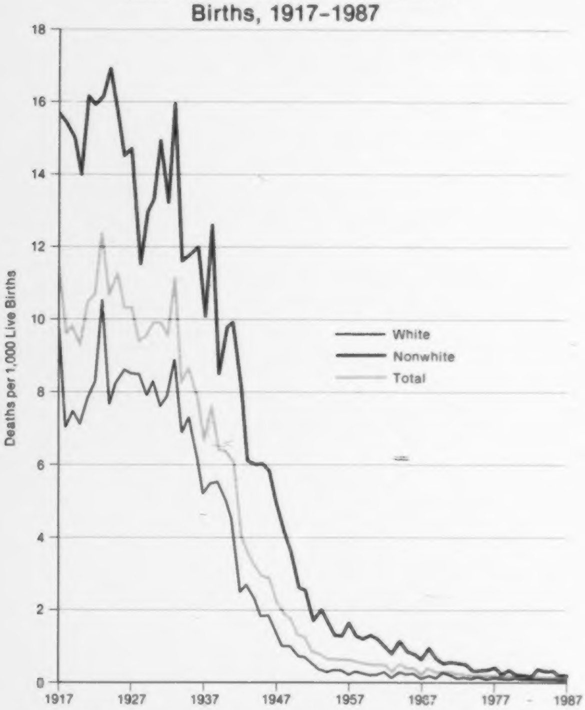
Major Causes of Maternal Deaths in the United States, 1988



Source: Adapted from Maternal Mortality in the U.S.: Report from the Maternal Mortality Collaborative, 1988.

The maternal death ratio measures the number of deaths per 1,000 live births. Since 1917, there has been a tremendous decline in the number of deaths among white and nonwhite mothers. The rate for the white population has always been lower than the rate for the nonwhite population. The current nonwhite ratio is more than double that of the white population, although both are below 0.25 maternal deaths per 1,000 live births.

Maternal Deaths Per 1,000 Live Births, 1917-1987



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1917-1987.

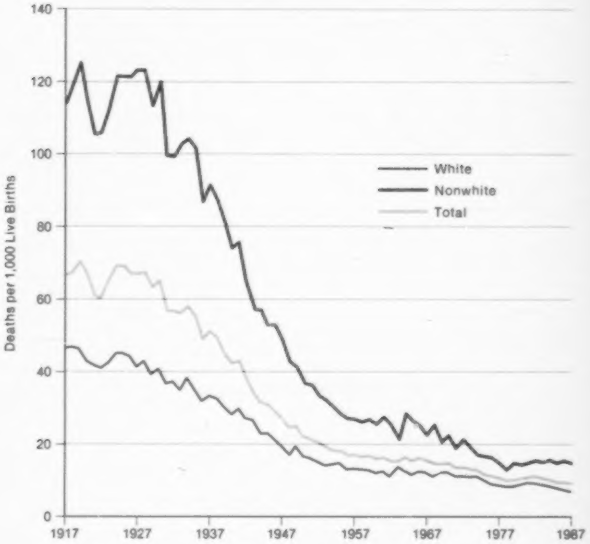
The reduction in maternal deaths is attributed to better medical care and earlier intervention than in the past. Educational efforts regarding drugs, alcohol, stress and nutrition have also assisted in making pregnancy safer.

The infant mortality rate is a ratio measuring the number of infant deaths which occur within the first year of life. Perinatal deaths include both fetal and neonatal deaths. A fetal death is defined as a death which occurs after 20 weeks gestation, and a neonatal death is a death which occurs within 28 days of a live birth. Thus, the perinatal death period ranges from 20 weeks gestation to 28 days after the live birth.

The fetal death ratio for Florida indicates the number of fetal deaths per 1000 live births. There has been a drastic decline in the number of fetal deaths during this century. Prior to 1941, the total number of fetal deaths never fell below 40.0 deaths per 1,000 live births. During this same period, the nonwhite fetal death rate was more than double the white rate. After 1940, the ratios declined and since 1953, the number of fetal deaths for the total population has not exceeded 20.0 deaths per 1,000 live births. The nonwhite rate continues to double that of the white population and is also greater than the total population ratio. Historical data reveal that there were more neonatal deaths, in absolute numbers, in 1960 and 1970, but since 1978, there have been more fetal deaths. Medical technology has greatly affected the probability that a premature child will survive beyond the first month of life.

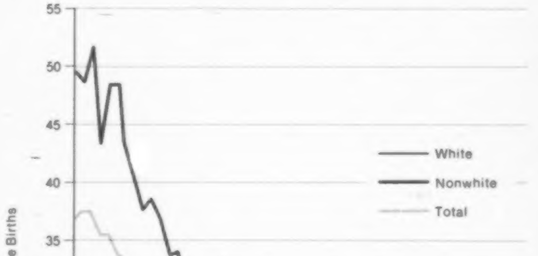
The neonatal death rate indicates the number of neonatal deaths per 1,000 live births. Florida began recording neonatal deaths in 1935. The neonatal death rate has declined significantly in the last 50 years to less than 10 per 1000 live births. The trends in the neonatal ratios are similar to those of the fetal death rates among the white, nonwhite, and total population. The development of neonatal intensive care units has greatly increased the probability of survival for many newborns, especially those born several weeks premature.

Fetal Deaths Per 1,000 Live Births, 1917-1987



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1917-1987.

Neonatal Deaths Per 1,000 Live Births, 1935-1987



Source: HRS Office of Comprehensive Health Planning based on Florida Vital Statistics, 1935-1987.

As indicated previously, the perinatal rate includes both the neonatal and fetal death rates. The national and state perinatal mortality rates have declined steadily since 1977. Florida dropped from a rate of 21.1 per 1000 births in 1977 to 15.8 in 1986, but the nonwhite deaths remained close to double that of white mortalities. Florida remained above the national average of 14.8 in 1986. Of the 2,819 perinatal deaths taking place in Florida in 1986, 1,218 (43.0%) occurred during the neonatal period. Thus, 57.0 percent of the deaths were stillbirths or fetal deaths.

Perinatal data for each county in Florida is based on the number of deaths from 1985 through 1987. The data indicate a statewide rate of 16.5 perinatal deaths per 1000 live births. Lafayette County had the lowest rate at 6.1, followed by Charlotte County at 9.0. Many of the counties in the northern portion of the state had perinatal death rates in excess of 20 per 1000 live births including Gadsden, Hamilton (the state's highest at 32.1), Jefferson, Leon, Putnam, Suwannee, Taylor and Walton. Glades County was the only county in southern Florida with a rate exceeding 20 per 1000 live births.

Forty percent of infant deaths occur within 24 hours of delivery, and the leading cause of death is unqualified immaturity, often due to low birth weight. Twenty-five percent of infant deaths occur between the first and seventh days of life. The leading cause of death during this period is respiratory distress syndrome. Eight percent of infant deaths occur during the second and fourth weeks with birth defects being the leading cause of death. Twenty-seven percent of infant deaths occur between one month and one year of life. The leading causes during this period are influenza and pneumonia.

The infant mortality rate shows infant deaths per 1000 live births. Historical data concerning the infant death rate, for both the white and nonwhite populations, show a significant decline since 1917. As with other mortality rates, the nonwhite population has historically and does currently have the highest mortality rate.

The overall rate of infant deaths is declining nationally and in Florida. Florida's rate was at the U.S. average of 10.8 deaths per 1,000 live births in 1984. In 1985, the rate increased to 11.3 deaths per 1,000 live births but declined to 10.5 in 1987. Again, the infant mortality rate among the nonwhite population is twice that of the white population.

Mortality

Statewide collection of mortality data began in 1917. Deaths are tabulated both by place of record (the county and state in which the death occurs) and by the place of residence (the county and state in which the decedent was a legal resident at the time of death). However, resident data have been tabulated only since 1933, when the interstate exchange of vital records began. Prior to 1933, only recorded data are available. Two kinds of death rates are figured: crude and age-adjusted. The crude death rate is computed by dividing the number of resident deaths by the population, while age-adjusted death rates are calculated using factors which allow for consideration of the effects of the age of the population. Age-adjusted rates are also better indicators of risk when comparisons of mortality are being made for sex or race subgroups of the population that have different age compositions. If the death rate is to be used to partially measure improvements in medicine, standard of living, or healthy lifestyle, the age effect must be removed. The direct method employing five age groups and the 1940 U.S. total population is used for age-adjusted rates in this atlas.

An analysis of Florida data beginning in 1920 indicates that the age-adjusted death rate has fallen steadily, a result of advances in medical science, public health, nutrition, and rising standards of living. This trend is similar to that of the United States as a whole. The crude rate in Florida also declined until about 1950, when the migration of elderly into the state increased. The age-adjusted death rate is expected to continue to decline but at a much reduced rate.

In 1987, a total of 126,955 deaths were registered in Florida, 3,415 more than in 1986. Contributing to the increased number of deaths were population growth and an increasing proportion of older persons. However, the 1987 crude death rate was unchanged from 1986 at 10.5 per 1,000 population; total and white age-adjusted death rates also remained unchanged. In contrast, the white age-adjusted death rate has declined steadily in the last ten years, from 5.4 per 1,000 in 1977 to 4.8 per 1,000 in 1987. The nonwhite rate, however, increased from 7.3 per 1,000 in 1977 to 7.7 per 1,000 in 1987, with some fluctuations over the ten year period.

Major Causes Of Deaths

The underlying cause of death is determined from death certificate medical information in accordance with procedures established by the World Health Organization (WHO) and the National Center for Health Statistics (NCHS). Standardized codes are assigned from the International Classification of Diseases (ICD).

The ICD is revised approximately every ten years to keep up with advances in medical knowledge. Revisions used in Florida were issued in 1917, 1921, 1930, 1941, 1949, 1958, 1968, and 1979. With each revision, the manner in which the causes of death were coded was modified, some of which involved major changes. Because of these revisions, year-to-year comparisons of deaths by cause can be misleading, unless such comparisons span a period of years in which only one revision was used or in which the changes from one revision to another were minor. To show Florida trends, this atlas includes cause of death trends from 1920 to 1987. Although this does not adequately account for the modifications in the ICD, it does show the fundamental cause of death trends over time.

The principal causes of death throughout most of recorded history have been communicable diseases. However, during the first half of the twentieth century, the disease mortality pattern in Florida and the United States has changed drastically from death by infectious or communicable diseases to death from non-infectious or chronic diseases. The trend data also reflect an increase in deaths due to violent means, such as homicide and suicide.

In 1927, four of the ten leading causes of death in Florida were communicable diseases: tuberculosis, pneumonia, diarrhea and enteritis, and syphilis; and four were chronic diseases: heart disease, nephritis (inflammation of the kidneys), cerebral hemorrhage (a form of cerebrovascular disease), and cancer. Death by automobile accidents was the only violent cause in the top ten. By 1947, two of the ten leading causes were communicable diseases: tuberculosis and pneumonia/influenza; and six were chronic diseases: heart disease, cancer, cerebral hemorrhage, nephritis, diabetes, and diseases of the arteries. Death by accidents (including automobile accidents) was the only violent cause in the top ten. By 1987, only one of the ten leading causes of death was a communicable disease - pneumonia/influenza - and six were chronic diseases: heart disease, cancer, stroke (cerebrovascular disease), chronic obstructive lung disease (COLD), diabetes mellitus, and chronic liver disease. Deaths due to violent causes had increased - suicide and homicide, as well as accidents, were ranked as three of the ten leading causes.

In the last sixty years, improvements in diagnosis, treatment, sanitation, nutrition, housing, working conditions, and preventive measures, such as immunizations, have greatly reduced communicable diseases. The increase in chronic diseases has been due in large part to the increased average life span.

Communicable Diseases

In the early 1900s, diphtheria and tuberculosis, both communicable diseases, caused many deaths. Today deaths from diphtheria are almost unknown, largely because of the mass immunization of infants. In 1900, tuberculosis was the leading cause of death in the United States after pneumonia/influenza (accounting for 11 percent of total deaths). This disease dropped to sixth place in 1950, accounting for only two percent of total deaths. In Florida, tuberculosis was the fourth leading cause of death in 1927 and the eighth in 1947. The tuberculosis death rate in Florida has decreased from 102.3 per 100,000 in 1920 to 1.2 per 100,000 in 1987.

Pneumonia, the second leading cause of death in 1900, is the only communicable disease still listed as one of the top ten leading causes of death today in Florida, ranking fifth in 1967 and sixth in 1927, 1947, and 1987. The death rate from pneumonia/influenza has decreased 68 percent since 1940, declining from 81.6 per 100,000 to 26.1 per 100,000 in 1987. Although the death rates from pneumonia have fallen, this disease still kills many elderly Floridians annually.

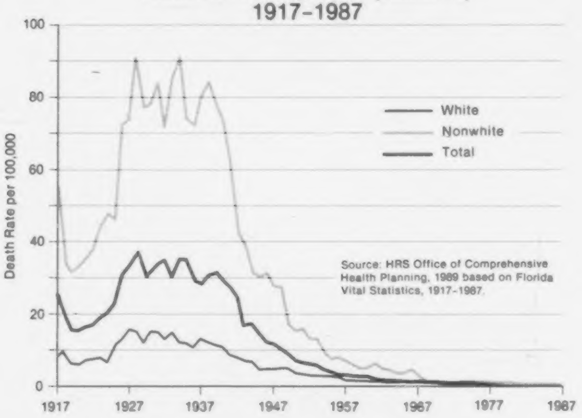
Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

Syphilis was the tenth leading cause of death in 1927 and the eighteenth in 1947. The death rate per 100,000 was 33.8 in 1927, but had dropped to 10.1 per 100,000 in 1947. Even though Florida's syphilis incidence is the highest in nearly thirty years (129.3 per 100,000 in 1987), it can be treated successfully at any stage and is no longer a leading cause of death. Death rates from syphilis in 1967 and 1987 were 1.1 per 100,000 and 0.1 per 100,000, respectively.

Resident Syphilis Crude Death Rates Per 100,000 Population, 1917-1987



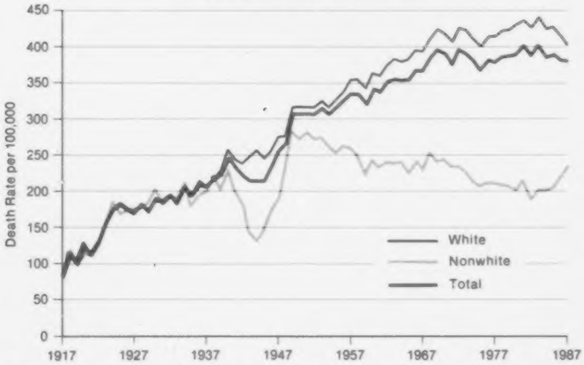
Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

Diarrhea and enteritis (inflammation of the intestine) was the seventh leading cause of death in 1927. By 1967, enteritis was listed as chronic enteritis and ulcerative colitis. In 1987, it was listed as regional enteritis and no longer considered a leading cause of death.

Chronic Diseases

In the past two decades, heart attacks have decreased more than 30 percent. However, even with those improvements, the death rate from heart disease has risen consistently. Heart disease was the second leading cause of death in 1920, ranking behind influenza/pneumonia, but it became the leading cause in 1921 and has retained that rank ever since.

Resident Heart Disease Crude Death Rates Per 100,000 Population, 1917-1987

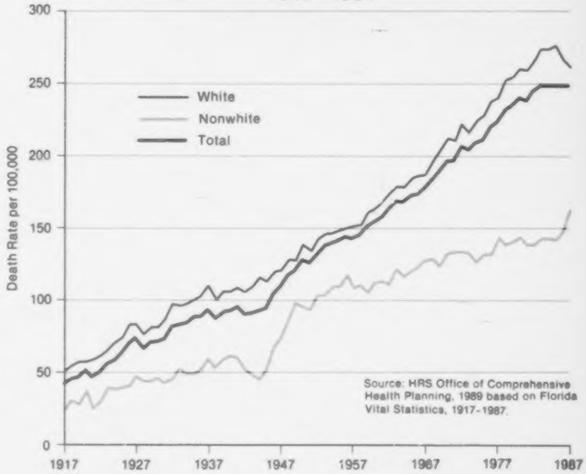


Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

The age-adjusted death rate has actually dropped by 30 percent in the past 25 years. The reasons for the decline include improved treatment of heart disease, such as advanced surgical techniques and pharmaceuticals, better control of hypertension, reduced prevalence of smoking, changes in personal health habits such as diet and exercise, and increased access to coronary care units.

Cancer, or malignant neoplasm, death rates have risen by a factor of 4.8 in 67 years, increasing from 51.3 per 100,000 to 247.7 per 100,000. This indicates that the populations in the age group with higher cancer death rates (65 and older) have grown faster than the total population. In 1927, cancer ranked as the fifth leading cause of death. However, it has ranked as the second leading cause of death for more than 40 years, ranking behind heart disease. The age-adjusted death rates for some cancers have decreased (breast and cervical), but others have more than made up the difference (lung).

Resident Cancer Crude Death Rates Per 100,000 Population, 1917-1987



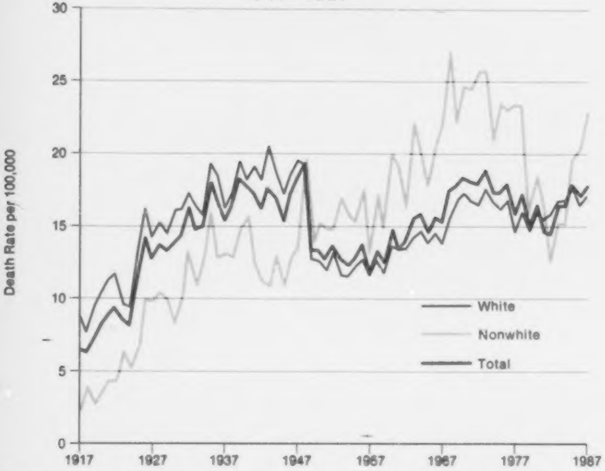
Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

Death rates from diabetes mellitus have increased by 115.9 percent since 1920. As a leading cause of death, diabetes mellitus has advanced in ranking from twentieth in 1927 to eleventh in 1937 to ninth in 1947 and to seventh in 1987. In Florida, deaths attributable to diabetes increase with the age of the individual.

Some form of cerebrovascular disease has ranked as the third leading cause of death for the past sixty years. In 1927 and 1947, the third leading cause was listed as cerebral hemorrhage; in 1967, it was listed as cerebrovascular disease; and in 1987, it was listed as stroke (cerebrovascular disease). Even though the terminology is different, each refers to a condition which prevents the brain from receiving blood.

Diseases of the arteries ranked as the tenth or eleventh leading cause of death in 1947, 1967, and 1987. Again, the terminology and coding have changed; in 1947, the tenth leading cause of death was listed as diseases of the arteries; in 1967, the tenth cause was general arteriosclerosis (hardening of the arteries). In 1987, atherosclerosis, previously referred to as arteriosclerosis, was the eleventh cause of death.

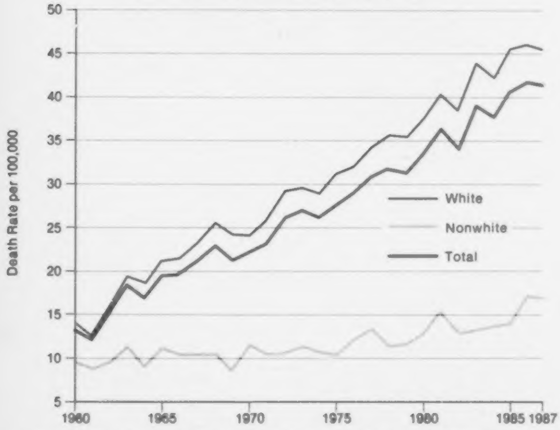
Resident Diabetes Crude Death Rates Per 100,000 Population, 1917-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

Emphysema was listed as the seventh leading cause of death in 1967. Emphysema is now included in chronic obstructive lung disease (COLD), along with bronchitis, asthma and other allied conditions. However, emphysema still results in the greatest number of deaths in this category. COLD has become increasingly important over the past several decades and has been the fifth leading cause of death in Florida since 1974. In 1960, its ranking was tenth. The death rate per 100,000 has also significantly increased since 1960, from 13.4 per 100,000 to 41.5 per 100,000 in 1987.

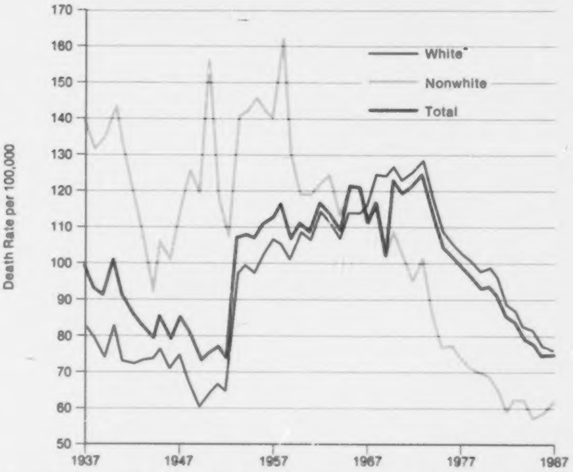
Resident Chronic Obstructive Lung Disease Crude Death Rates Per 100,000 Population, 1960-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1960-1987.

Cirrhosis of the liver was the twentieth cause of death in 1947. From 1920 to 1973, crude death rates from cirrhosis increased steadily from 6.4 per 100,000 in 1920 to 20.9 per 100,000 in 1973. After 1973 crude death rates declined, but cirrhosis was the ninth leading cause of death in 1967 and 1987. Crude death rates in 1967 and 1987 were 16.2 per 100,000 and 13.7 per 100,000, respectively.

Resident Stroke Crude Death Rates Per 100,000 Population, 1937-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1937-1987.

Nephritis was the second leading cause of death in 1927 with a crude rate of 121.1 per 100,000 and was the fifth leading cause in 1947 with a crude rate of 62.6 per 100,000. However, in 1987, the rate had dropped to 0.3 per 100,000. Nephritis was responsible for the deaths of only 33 people in Florida.

Resident Cirrhosis Crude Death Rates Per 100,000 Population, 1917-1987

An aortic aneurysm is a localized abnormal enlargement of the aorta, filled with fluid or clotted blood and resulting from disease of the vessel wall. In Florida, deaths attributable to aortic aneurysm increase with age. In 1987, 85 percent of all deaths from this cause were to individuals 65 years or older. Aneurysm was not a leading cause of death in either 1927 or 1947. But, with the aging of the population, by 1967, it ranked eighth and, in 1987, it ranked twelfth.

Violent Deaths

Accidents and other violent incidents are the leading cause of death of Floridians aged 1 to 44. Accidents, suicides, and homicides combined accounted for 8,584 deaths in Florida in 1987. Accidents killed 4,970 Floridians, with motor vehicle accidents alone accounting for 2,939 deaths. Suicide was responsible for 2,005 deaths, and 1,491 Floridians were the victims of homicide.

In 1927, accidents resulting from various situations were ranked separately as leading causes of death. As a result, automobile accidents alone ranked as the ninth leading cause of death and accidental drownings ranked seventeenth. If all accidents for that year are included in one grouping, that grouping becomes the third leading cause of death.

By 1947, all accidents were grouped together as one leading cause including motor vehicle, falls, drownings, poisonings, firearms, railway, boating, lightning, and others. Deaths by all accidents have ranked as the fourth leading cause since 1947. If motor vehicle accidents had remained a separate leading cause of death, as in 1927, its ranking would have been eighth in 1947, fifth in 1967, and sixth in 1987. All other accidents excluding motor vehicle accidents would have ranked fourth in 1927, fifth in 1947, fourth in 1967, and seventh in 1987.

Not until the 1950s did other violent means become a leading cause of death. Suicide became a leading cause of death in 1954, ranking between ninth and twelfth until 1981. Since 1981, suicide has ranked either seventh or eighth. In 1987, it ranked eighth and was the third cause of death for the 15- to 24-year-old age group.

In 1927, homicides by various means were grouped separately as a leading cause of death. Homicide by firearms ranked as the thirteenth leading cause of death. If all homicides for that year are included in one grouping, that grouping becomes the ninth leading cause of death. Homicide from all causes became a leading cause of death in 1967, ranking twelfth. Since 1984, homicide has ranked as the tenth leading cause of death with a total rate of 12.3 per 100,000 in 1987. Young nonwhite males are victims of homicide at a disproportionate rate. In 1987, the crude death rate for nonwhite males was 61.4 per 100,000 compared to white males at 11.7 per 100,000. Violent deaths by accident, suicide, and homicide are the three leading killers of young males, both white and nonwhite, between the ages of 15-24.

Maternal and Infant Mortality

In 1927, death due to the puerperal state (the period of confinement after labor) was ranked as the eleventh cause of death. This grouping included abortion; ectopic gestation; toxemias of pregnancy; hemorrhage of childbirth and puerperium; infection; and other diseases, accidents and conditions of childbirth and puerperium. In 1987, these conditions are grouped as maternal causes and resulted in only 17 deaths in Florida.

In 1927 and 1947, premature birth was listed as the eighth and seventh leading cause of death, respectively. Also, in 1967, diseases peculiar to early infancy ranked as the sixth leading cause of death. This grouping included birth injuries, postnatal asphyxia, infections of the newborn, hemolytic disease of the newborn, immaturity, and all other defined and ill-defined diseases of early infancy. Today these causes of death are listed as perinatal conditions and are no longer a leading cause of death.

1987 Mortality

The ranking of the ten leading causes of death in 1987 did not change from 1986 and changed only slightly from 1977. Seven of the leading causes had the same ranking as in 1977. However, diabetes increased from ninth to seventh, chronic liver disease declined from seventh to ninth, and homicide increased from eleventh to tenth.

Beginning with mortality data for 1987, human immunodeficiency virus (HIV) was added as a new cause of death, ranking thirteenth. The total number of deaths due to HIV infection during 1987 was 1,095, with 641 white deaths and 454 nonwhite deaths. Death rates from this cause were higher for males than for females and also higher for the nonwhite population (25.1 per 100,000) than for the white population (6.2 per 100,000). For both males and females, death rates were highest for the age group 25-44.

From 1977 to 1987, the three leading causes of death remained the same for whites; heart disease, cancer and stroke. COLD increased to fourth, while accidents declined to the fifth leading cause. Pneumonia and influenza remained sixth, suicide increased to seventh from eighth and diabetes increased from tenth to eighth.

For nonwhites, the five leading causes were the same as ten years ago: heart disease, cancer, stroke, accidents and homicide. Human immunodeficiency virus ranked sixth; followed by perinatal conditions which increased from ninth to seventh. Diabetes declined from seventh to eighth; pneumonia and influenza declined from sixth to ninth; and COLD remained at tenth.

Leading Causes of Death in Florida, 1927, 1947, 1967, 1987

Cause of Death	Year	Rank	Deaths			Crude Death Rate per 100,000		
			Total	White	Nonwhite	Total	White	Nonwhite

	1987	NR	33	28	5	0.3	0.3	0.3

Notes:

1. Pneumonia rates only for 1927 and 1947.
2. All homicides grouped together and ranked for comparison purposes for 1927; report lists Homicide by Firearms as a leading cause.
3. Motor Vehicle Accidents for 1947, 1967 and 1987 ranked separately for comparison purposes.
4. All accidents for 1927 ranked for comparison purposes.
5. Most recent estimates of population for each year were used for rate computations.
6. Changes in ICD coding have affected categorization of deaths by cause over time, thus data may not be exactly comparable.

NR - Not ranked in top twenty causes.

Life Expectancy

Life expectancy for a given year is the number of years that a baby born in that year will live if it experiences the same death rates at every age that the population has experienced in that year. This statistic is usually calculated for specific race and sex groups and, in Florida, is usually calculated using data from three years, centered on the midyear. Between 1920 and 1980, overall life expectancy increased 18.7 years, from 55.3 years to 74.0 years.

Based on 1980 data, all four major race/sex groups continue to show increases in life expectancy at birth. White females maintain the greatest life expectancy at 78.9 years, followed by nonwhite females at 72.4, white males at 71.1, and nonwhite males at 63.8. Before 1980, white males had a greater expectancy at birth than nonwhite females. White females and nonwhite males have maintained the top and bottom positions, respectively, for the past fifty years.

Years Of Potential Life Lost

To determine the relative importance of various causes of death, one can calculate the estimated years of potential life lost (YPLL). YPLL is an estimate of the total number of years of life which are lost as a result of dying prior to the age of life expectancy. The age of 65 was used in these calculations to represent the minimum life expectancy, about age 65 for non-white males in 1987. Thus a death at age 50 represents 15 YPLL. The computations were further simplified by grouping the ages and using the midpoint of the age group as a median. For example, 300 deaths at ages 45-54, median age 50, would represent 4,500 YPLL.

Deaths in the young age groups, especially those under 15, have a large effect on the total YPLL. For example, a death in the 1-14 age group represents approximately 58 YPLL, whereas one in the 35-44 age group represents 25 YPLL, and one in the 55-64 age group only about 5 YPLL.

Although a certain cause may result in many deaths, the corresponding YPLL will be lower for a cause of death affecting older people and higher for a cause affecting younger people. The actual numbers of deaths from specific causes are less important when comparing YPLL by cause. For example, fatal injuries claimed 4,079 lives of individuals between the ages of 1 and 65, with 141,462 potential years of life lost, whereas heart disease claimed the lives of 6,986, with only 72,944 YPLL.

Deaths by violent means (all accidents, homicides, and suicides) represented 6.8 percent of all deaths of Florida residents and 21.5 percent of all deaths due to specific major causes of Florida residents under age 65. However, violent deaths represented 233,209 YPLL or 42 percent of all YPLL.

Heart disease, cancer, and stroke accounted for 66.8 percent of all deaths of Florida residents and 51.4 percent of all deaths by specific major causes of Florida residents between the ages of 1 and 65, yet accounted for only 31.7 percent of all YPLL. Correspondingly, all of the major chronic diseases represent 72.4 percent of all deaths or 53.2 percent of deaths due to specific major causes for those under 65 years and represent 34.1 percent of YPLL. This demonstrates that chronic disease mortality is related to aging of the population and is considerably less important in terms of YPLL than is represented by the actual numbers of deaths.

Years Of Potential Life Lost Before Age 65 For Specific Causes in Florida, 1987

Disease	Total Deaths	Years of Potential Life Lost						
		1-14	15-24	25-34	35-44	45-54	55-64	Total<65

Violence

Accidents, homicides, and suicides are considered violent deaths. Combined, these three causes accounted for 8,584 deaths in Florida in 1987. Accidents killed 5,088 Floridians, with motor vehicle accidents accounting for 2,939 deaths. Suicide was responsible for 2,005 deaths, and 1,491 Floridians were the victims of homicide. Since 1917, the accidental death rate has decreased, while suicide and homicide death rates have increased.

Accidents

Accidents are the fourth leading cause of death in Florida. They are the leading cause of death for Floridians between the ages of one and 34 and the third leading cause of death for people between the ages of 35 and 44. People 75 and older have the highest accident rate of any age group - 106.7 per 100,000 persons in 1987.

Motor vehicle accidents are the most frequent cause of accidental death in Florida. The combined rate of death due to falls and drowning, the second and third leading causes of accidental death, is less than half of the motor vehicle death rate.

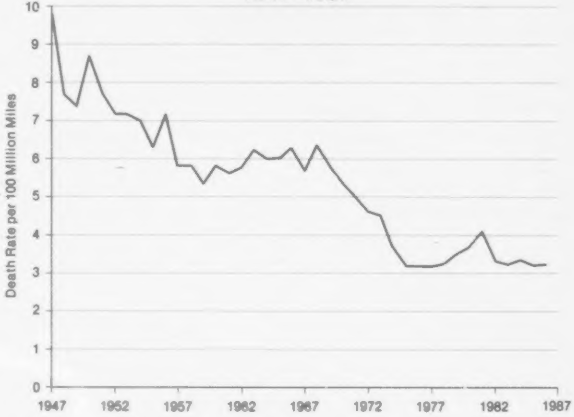
Motor Vehicle Accidents

Accidental deaths due to motor vehicles include deaths to drivers (motorcycle and automobile), passengers, pedestrians and pedalcyclists. In 1941, the Florida Regulatory Traffic Law was enacted. This law required motorists and law enforcement officers to report to the State Department of Public Safety traffic accidents in which a person was killed or injured or which resulted in total property damage of $50 or more. The earliest data that are available from the now Department of Highway Safety and Motor Vehicles (DHSMV) is from 1947. In 1947, 10,451 motor vehicle accidents were reported - 772 fatalities and 6,365 injuries. By 1987, the total number of motor vehicle accidents in Florida had increased to 240,429. In 1987, DHSMV reported 2,621 deaths and 134,465 injuries caused by motor vehicle accidents. (This number differs from Vital Statistics records since people who die from complications after the accident report is filed will not be considered in DHSMV statistics as fatalities).

Based on gasoline sales, DHSMV determines the number of motor vehicle miles traveled in Florida and calculates a death rate per hundred million miles. Despite the increased incidence of motor vehicle deaths in Florida, the rate of motor vehicle accidents per hundred million miles of vehicle travel has decreased. In 1947, there were an estimated 9 billion motor vehicle miles traveled with a death rate per hundred million vehicle miles of 9.7. In 1986 there were an estimated 87.3 billion motor vehicle miles traveled, with a death rate per hundred million vehicle miles of 3.3.

The decrease in the rate of motor vehicle accidents can be attributed to improvements in four areas: education, enforcement, engineering and emergency medical services. Better driver education and public safety awareness, better enforcement of traffic laws, better road and vehicle engineering and better pre-hospital and trauma care have each been a factor. The steady decrease in the rate of deaths due to motor vehicle accidents during the period between 1969 and 1975 and the relative stability of the death rate since 1975 show the impact of federal and state initiatives.

Motor Vehicle Deaths Per 100 Million
Miles of Vehicle Travel
1947-1987



Source: Department of Highway Safety and Motor Vehicles, 1947-1987.

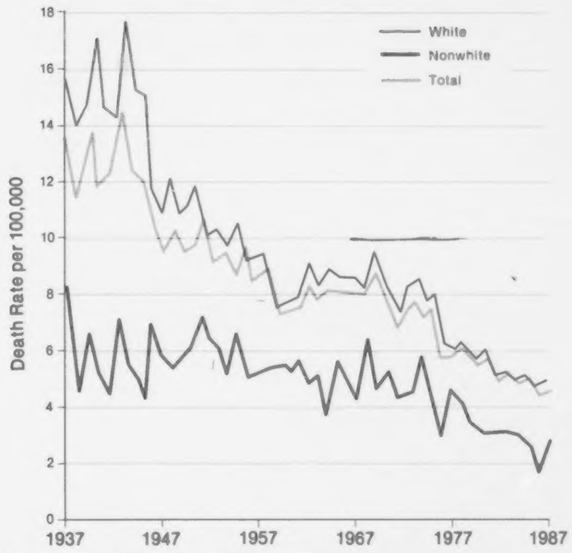
The 1966 Federal Highway Safety Act required more stringent motor vehicle and roadway safety standards than before. Among the requirements of this legislation were the mandatory installation of seatbelts in passenger cars, beginning in 1967, and the reconfiguration of vehicle dashboards. The National Highway Traffic Safety Administration (NHTSA) was also established in 1966. NHTSA establishes national motor vehicle safety and special purpose standards; investigates alleged safety defects in vehicles; maintains a national driver register; and provides grants to the states to support public service programs promoting motor vehicle and traffic safety. The reduction of the speed limit in Florida to 55 miles per hour in January 1974 and the provision and oversight of emergency medical services in Florida, mandated by the Florida Emergency Medical Services Act of 1973, also contributed to the decrease and subsequent stabilization in the death rate.

Alcohol is a major cause of traffic accidents and fatalities. Between 1983 and 1987, more than half of the motor vehicle fatalities were alcohol-related. During this time, 8,149 Floridians died in alcohol-related accidents. In 1987, 51.9 of all motor vehicle fatalities were alcohol-related. According to data compiled by the Florida Department of Law Enforcement (FDLE), the number of persons arrested Driving Under the Influence (DUI) between 1971 and 1988 has increased 45 percent, from 29,172 to 64,260. (Although alcohol use was indicated in early motor vehicle accident reports, there was no formal system for identification, reporting and measurement. Therefore early data on alcohol use by drivers cannot be compared with current data.)

Falls

The death rate due to falls and complications from falls has shown an overall decrease in Florida since 1917. In the last five years, however, an average of 547 Floridians annually have died from falls or complications from falls. Deaths due to falls and their complications surpass even motor vehicle fatalities as the leading cause of accidental death for people over the age of 75. In 1987, Floridians over 75 had a death rate due to falls of 38.2 per 100,000 persons. This was more than eight times greater than the statewide rate of 4.6 per 100,000 persons. The death rate of whites due to falls and complications from falls has consistently been double the rate of nonwhites.

Resident Death Rates Due to Falls, 1937-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1937-1987.

Trips and falls occur for many reasons. Many are caused by safety hazards, especially in the home, while others occur due to physical limitations or impairments of vision, hearing or memory. Other causes of falls include: orthostatic hypotension (a momentary drop in blood pressure), which may occur when a person rises; heart irregularity, which can temporarily prevent the heart from pumping enough blood to the brain and cause unconsciousness; changes in the balance of the inner ear; arthritis, which reduces muscle tone and strength; and osteoporosis which weakens the structure of bones. Alcohol, sleeping pills, and drugs used for depression, high blood pressure and angina may also contribute to a person's risk.

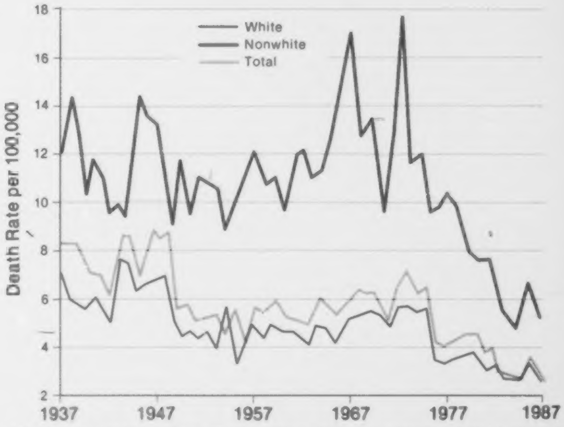
Drowning

Drowning is a form of suffocation ("asphyxia"), which typically begins with a panic and a struggle. The victim may unsuccessfully attempt to hold his breath but exhales air instead, and then inhales water into the breathing passages. Loss of consciousness, seizures, cardiac arrest and death may follow. In 85 percent of the fatalities, the lungs contain fluid. In other cases persistent spasm of the vocal cords causes suffocation and no fluid enters the lungs.

Florida contains almost 10 percent of the nation's tidal shoreline (which includes the lengths of shoreline of outer coast, offshore islands, sounds, bays, rivers, and creeks to the head of tidewater). Its 8,426 statutory miles of shoreline is the longest of any of the contiguous states. Florida also has approximately 22,000 public swimming pools and a large number of private residential swimming pools, which are used almost year-round in many areas. The availability and accessibility of swimming, boating and fishing in recreational areas all contribute to Florida's drowning death rate, which has been consistently higher than national rates.

Death rates due to drowning have shown an overall decline since 1917. Florida's highest annual drowning death rate (8.58 per 100,000 persons) occurred in 1946 and 1948. Florida's lowest annual drowning death rate (2.97 per 100,000 persons) occurred in 1985. Although more whites than nonwhites become drowning victims, in most years the nonwhite death rate due to drowning has been almost double the rate of whites. Exceptions from this trend occurred in 1943-45 when the rate of nonwhites decreased to within 150 percent of the rate of whites, and in 1956, 1963, 1968, 1973 and 1976 to 1979, when it was triple the drowning rate of whites.

Resident Death Rates Due to Drowning, 1937-1987



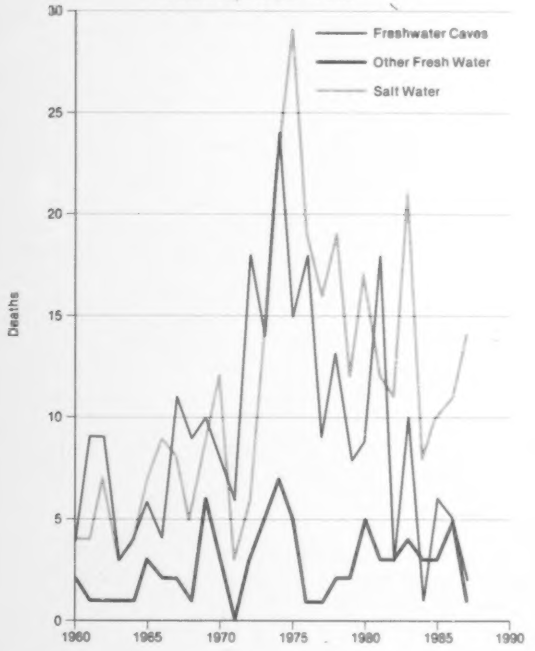
Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1937-1987.

The circumstances of drowning deaths differ by age groups. Infants younger than one year most frequently drown when they are left unattended or unsupervised in bathtubs or pools. Children between the ages of one and four have the highest death rate due to drowning than any age group. They frequently wander into unenclosed backyard pools or are unsupervised in swimming pools, lakes and ponds. Drowning victims between the ages of 5 and 15 often overestimate their swimming skills. An increasing number of nonwhite drowning victims fall in this age group. Drowning deaths in adolescents and adults are often associated with alcohol or other drugs. Alcohol intoxication results in poor judgement, easy fatigability and may affect the body's protective mechanisms against drowning, such as the mammalian diving reflex and laryngospasm. Many elderly persons drown as a result of a fall in a bathtub or a fall into a pool or canal. There is speculation that a number of elderly drowning deaths are actually suicides.

Skin and Scuba Diving Accidents

Deaths occurring to skin and scuba divers are not directly classifiable by ICDA codes. Because of the increasing popularity of skin and scuba diving in Florida, the Office of Vital Statistics has been keeping special records of skin and scuba diving fatalities since 1960. Between 1960 and 1987, 647 persons have drowned while skin or scuba diving in Florida waters. Of this group, 91 percent (589) have been white males and 43 percent (280) have been between the ages of 20 and 29. Fatalities occurred almost equally in salt water (48.6 percent) and in fresh water (51.3 percent). The majority of fresh water fatalities (77 percent) occurred in underwater caves. Most of the deaths (81 percent) occurred using scuba equipment rather than just snorkel equipment (18 percent) or an air hose (1 percent). Only 4 percent of the fatalities were job related. The most fatalities (53) were recorded in 1974, and the least number of fatalities (7) were recorded in 1963.

Florida Skin and Scuba Diving Deaths, 1960-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1960-1987.

Firearm Accidents

Since 1937, 3,809 Floridians, an average of 75 per year, have been accidentally killed by firearms. The majority of those accidentally killed by firearms are under the age of 24. In 1986, for example, 50 persons were accidentally killed by firearms in Florida. Of this group 40 or 80 percent were younger than 24.

Except for 1985, the nonwhite death rate due to accidental shootings has been higher than the rate of whites. In many years the nonwhite rate was double and even triple the white rate. In 1947, it was almost four times greater than the white rate. Only in 1949, 1977 and 1980 were the rates about the same.

Accidental deaths due to gunshots can occur under many circumstances. The most frequent victims are children playing with loaded guns that they have found in the home and hunters. Many gunshot injuries result in head injury or complete or partial spinal cord injury.

Resident Death Rates Due to Firearm Accidents, 1937-1987

Florida Unique Incidence Accidents

There are several types of accidents that because of Florida's unique geographic location and climate occur more frequently in Florida than in other states. These accidents do not cause a large number of deaths or injuries but occur with enough frequency that they are closely monitored. Two of these are lightning strikes and alligator attacks.

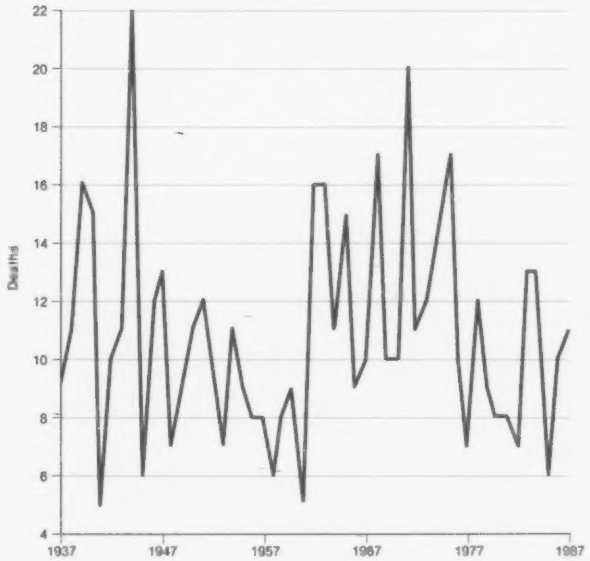
Lightning

Every year lightning kills more people than any other natural disaster, with the exception of flash floods. Nationally, the U.S. Census Bureau reports an average of 500 persons killed and 1,500 injured each year. Annually lightning strikes every square mile of the United States 30 to 40 times, destroying more than $60 million worth of property, exclusive of losses from approximately 7,000 forest fires started by lightning.

Florida leads the nation in deaths due to lightning. Between 1937 and 1987, 533 Floridians have been killed by lightning -- an average of 11 deaths annually. Florida's high number of lightning deaths can be attributed to two factors: the high occurrence of thunderstorms in Florida and the year-round outdoor lifestyle of Floridians. Lightning is a natural, short-lived, high-current electrical discharge in the atmosphere. The cumulonimbus clouds of thunderstorms are the most frequent producers of lightning. As many as 100 days a year in Florida are marked by thunderstorms -- some of them isolated and occurring suddenly. More than half of the people killed by lightning are engaged in outdoor recreational activities. People are most likely to be struck by lightning if they are in an open field, under a tree, or on or near water. The climate and availability of outdoor recreational activities in Florida combine to increase the risk to Floridians of being struck by lightning.

Lightning can also cause varied and severe injuries. Lightning strikes carry the force of an explosion. Victims can be hurled into the air and knocked into obstacles or onto the ground. A bolt of lightning can tear off a victim's clothes and knock down several people at once. Arrhythmia (irregular heartbeat), tachycardia (too quick a heartbeat) or cardiac arrest can occur. Diminished vision or blindness can result from retinal detachment or disruption of the optic nerve. Cataracts can develop months or even years later. Lightning can rupture the ear's tympanic membrane (eardrum), which can result in a hearing impairment. Unconsciousness, seizure, paralysis, mental confusion and amnesia often develop soon after the incident and disappear within a few hours. Psychological neuroses may occur. Most burns caused by lightning are not severe. Typical burns include "light feathering" or redness, and, in many cases, there is no scarring. Internal injuries are uncommon but in severe cases lightning can affect blood vessels and muscles.

Resident Deaths Due to Lightning, 1937-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1937-1987.

Alligator Attacks

Alligators are found in only two parts of the world: the Yangtse River valley in China and the southeastern United States. Alligators are prehistoric reptiles and play an important role in the ecology of Florida's wetlands. Since the Florida Game and Fresh Water Fish Commission began tracking alligator attacks in 1948, only 103 alligator attacks against humans have been reported. Five of these attacks were fatal.

Since 1972, there have been about six alligator attacks a year in Florida. In 1977, there were 14 reported attacks, and in 1986, there were 13 reported attacks. Only two attacks were reported in 1976, 1979 and 1988. Fatal attacks occurred in Sarasota County in 1973; in Charlotte County in 1977 and 1988; in St. Lucie County in 1984; and in Wakulla County in 1987.

It is illegal to feed alligators in Florida because although alligators have a natural fear of humans, it is diminished when people regularly feed them. When this occurs alligators are more likely to attack. Many attacks are defensive. Alligators will attack to protect their young. When a snorkler or swimmer bumps into a submerged or partially submerged alligator, the alligator reacts by grabbing the swimmer with its jaws.

Alligator attacks occur during every month of the year but are more common in the summer months. During the cooler months, alligators are inactive and bury themselves in muddy lake bottoms and river banks. When they are active, alligators tend to feed at dusk or at night.

The Florida Game and Fresh Water Fish Commission's nuisance alligator program receives approximately 7,000 "nuisance gator" complaints each year. Approximately half of these complaints warrant removal of the alligator.

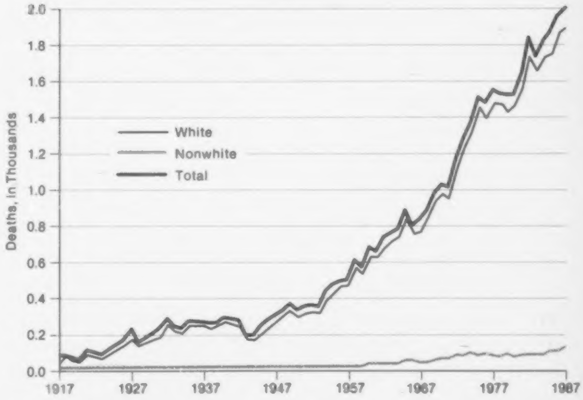
Suicide

Suicide is defined as the act or instance of taking one's own life voluntarily and intentionally. The *Florida Statutes* do not classify suicide or attempted suicide as a crime, but do classify "assisting in self-murder" as manslaughter.

Suicide was the eighth leading cause of death both nationally and in Florida in 1987. Although suicide represents only an approximate 1.5 percent of all deaths, it is especially tragic since it can be prevented. For every suicide it is estimated that there are an average of 31 productive years of life lost as a result of premature, unnecessary and wasteful death. For example, the 2,005 suicides in Florida during 1987 resulted in 36,040 potential years of life lost.

Both the rate and number of suicides in Florida have increased steadily. More whites commit suicides than nonwhites. Since 1917, there were 20 white deaths due to suicide for every nonwhite death. Successful suicides reveal only a portion of the problem. The National Center for Health Statistics estimates that for every successful suicide there are 50 attempted suicides. Guns are used in 59 percent of successful and attempted suicides.

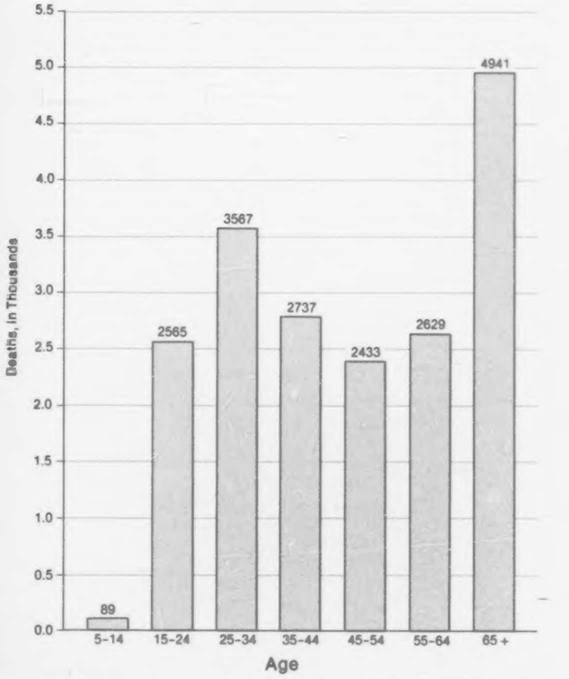
Resident Suicide Deaths, 1917-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1917-1987.

Of particular concern are the suicide rates among persons between 15 and 24 and persons over 65. Between 1960 and 1987, the suicide rate of persons between 15 and 24 more than doubled in Florida, increasing from 6.6 per 100,000 persons to 13.0 per 100,000 persons. Persons over the age of 65 have consistently had the highest suicide rate of any age group. The suicide rate for this group has shown a slight decline, going from 26.0 per 100,000 persons in 1960 to 23.9 in 1985.

Suicide is the third leading cause of death for adolescents and young adults. Although suicide rarely occurs before age 12, the rate rapidly increases after this age. White males between 20 and 24 are at the highest risk for suicide among young people. The number and rate of suicides in this age group are nearly twice as high as those for 15 to 20 year olds.



Suicide Deaths by Age Group, 1978-1987

Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1978-1987.

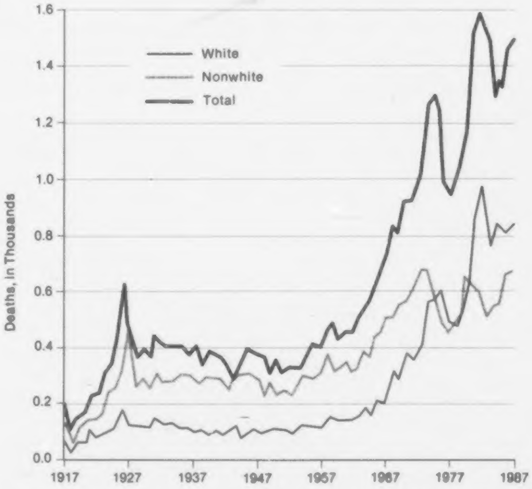
Homicide

As defined by the *Florida Statutes*, homicide includes the crimes of murder and manslaughter. Murder is "the unlawful killing of a human being; when perpetrated from a premeditated design to effect the death of the person killed or any human being (Section 782.04, *F.S.*)." Manslaughter is "the killing of a human being by the act, procurement, or culpable negligence of another, without lawful justification ...(Section 782.07, *F.S.*)." Manslaughter is further classified as non-negligent manslaughter or manslaughter by negligence. Non-negligent manslaughter is reported with murder in the annual Uniform Crime Report compiled by the Florida Department of Law Enforcement.

In 1972, there was a homicide committed in Florida every 9.5 hours. By 1987, the incidence of homicide had increased to one every 6.4 hours. Since 1960, Florida's age-adjusted homicide rate has increased from 10.1 per 100,000 persons to a peak of 16.8 per 100,000 in 1980. Since 1980, however, the rate has decreased to 13.1 per 100,000 persons. Florida's age-adjusted homicide rate consistently exceeds the national age-adjusted homicide rate.

The circumstances of murder in Florida have changed considerably since 1971. In 1971, 30 percent of all homicides in Florida resulted from an argument within the family, and only 6.7 percent were crime related. By 1987, the number of family related homicides represented only 12.2 percent of all homicides, while crime related homicides represented 42.8 percent of all homicides. In 1972, alcohol-related homicides represented 9.3 percent of all homicides. In 1987, alcohol-related homicides represented only 4.5 percent of all homicides. Conversely the percentage of homicides associated with narcotics has increased. In 1983, 5.6 percent of all homicides were narcotics related. By 1987, this percentage had almost doubled. Narcotics-related homicides represented 10.0 percent of all homicides in Florida in 1987.

Males have consistently represented between 70 to 73 percent of all homicide victims and from 80 to 84 percent of all those arrested for homicide in Florida. The percentage of victims and perpetrators by race, however, has been changing. In 1971, 59.4 percent of homicide victims and 69.3 percent of those arrested for homicide were nonwhite. In 1987, 42.3 percent of the homicide victims were nonwhite and 49.9 percent of those arrested for homicide were nonwhite. Prior to 1976 there were annually more nonwhite homicide victims than white homicide victims. The nonwhite homicide rate, however, has been consistently higher than the white homicide rate. In many years (1941, 1944-1948, 1950, 1953, 1956, 1957, 1959, 1961, 1964) the nonwhite homicide rate has been as great as ten times the white homicide rate. In recent years the nonwhite homicide rate has declined to an average of four times the white rate.



Resident Homicide Deaths, 1917-1987

Child Abuse

Child abuse may involve the physical or sexual maltreatment of a child or the neglect of a child's needs. Almost 150,000 cases of child abuse were reported in the 1987-88 fiscal year; over 27,000 cases were confirmed. Child abuse in Florida decreases as children grow older: 38 percent of reported cases involve children under 5, 30 percent involve children 5-9, 22 percent involve those 10-14 and 10 percent involve adolescents 15-19. Approximately 11 percent of Florida child abuse reports involved sexual abuse. Although deaths resulting directly from child abuse are few in number, other violent deaths can be traced to such abuse -- suicides of sexually abused teenagers, homicides of parents by abused children and homicides by criminals who were abused as children.

Reported Cases of Child Abuse by Age, FY 1982-83 through FY 1987-88

Chronic Diseases

Chronic diseases are noncommunicable, that is they are neither infectious nor contagious and are not transmitted by personal contact. Chronic is loosely defined as being of slow onset and long duration. This section addresses six primary chronic diseases - cancer, chronic obstructive lung disease, cirrhosis, diabetes mellitus, heart disease and stroke. Each of these six diseases is currently among Florida's ten leading causes of death.

Total deaths from these six diseases have significantly increased since 1917 or since they were first recorded. However, deaths from cancer, heart disease and COLD have shown the greatest increases and have shown the most continuous rise in total numbers. Cancer deaths have increased by a factor of 78.1 since 1917, while heart disease deaths have increased by a factor of 58.9. COLD has been a cause of death grouping since 1960. Total deaths have increased by a factor of 7.5 since that time. Cirrhosis and stroke have also shown significant increases in the number of total deaths, however both have, over the past fifteen years, shown only minor increases. Since 1917 cirrhosis deaths have increased by a factor of 19.3 and stroke deaths have increased 5.2 since 1937.

To account for modifications in the International Classification of Disease codes, 1970 is used as the baseline year in the data on age-adjusted mortality rates for each specific disease. It should be noted that chronic disease death rates are higher among older persons than younger persons. Thus, when death rates are shown for counties those with greater proportions of older persons tend to have higher crude death rates for these diseases and counties with greater proportions of younger persons tend to have lower crude death rates.

Chronic Disease Risks

Chronic diseases share two common characteristics:

- the symptoms or effects of the disease occur over an extended period of time and
- the diseases share common risk factors.

Since chronic diseases usually develop over many years, individual behavior has a much greater effect on these diseases than other factors. Environmental risk factors such as exposure to asbestos, radon, radioactive substances, cigarette smoke, cadmium and other carcinogenic substances do play a role in the development of chronic diseases, but these factors are in part subject to change by individual action. An individual, knowing of the dangers of certain substances, can often move away from their source. A person has a much higher risk of acquiring one or more chronic diseases as a result of individual lifestyle practices. Chronic disease risks increase when a person abuses alcohol, has an elevated serum cholesterol level, has a diet high in fat and low in fiber, has a high sodium intake, lives a sedentary lifestyle, is hypertensive, smokes, is under stress, or is overweight. A family history of chronic disease is also a major risk factor since a predisposition to certain diseases may be hereditary. Finally, the presence of other chronic diseases can increase the risk of certain related diseases.

Chronic Disease Risks

Disease/ Condition	Environmental Risk Factors	Behavioral Risk Factors	Other Risk Factors	Florida Mortality Risk Per Million Population	
				1970	1987
Breast Cancer	Radiation exposure		Family history Age over 50 Late childbearing Late menopause/menarche Having no children	154	186
Heart Disease		Smoking High blood pressure High cholesterol diet High fat, low fiber diet High sodium intake Stress Alcohol abuse Lack of exercise	Diabetes Age over 65 Presence of other chronic diseases	3,911	3,776
Cervical Cancer		Sexual activity at an early age or with multiple partners		37	20
Chronic Obstructive Lung Disease	Air pollution	Smoking	Family history	251	412
Cirrhosis		Alcohol abuse Drug abuse	Diabetes Pancreatitis Ulcers in the colon	176	137
Colorectal Cancer		High fat, low fiber diets	Family history Age over 40 Ulcers in the colon	240	284
Diabetes Mellitus		Obesity Lack of exercise Improper diet Stress Improper insulin control	Family history Age over 35	184	177
Lung Cancer	Radiation exposure Air pollution Asbestos exposure Cigarette smoke exposure	Smoking		505	762
Prostatic Cancer	Cadmium exposure	High fat, low fiber diet	Family history Age over 40	102	163
Stroke		Smoking High blood pressure High cholesterol diet High fat, low fiber diet High sodium intake Stress Alcohol abuse Obesity	Diabetes Cardiac impairment	1,240	737

Cancer

Cancer includes a group of related diseases that are characterized by the abnormal, uncontrolled growth and spread of body cells. Cancerous cells continue to divide and, unlike most normal cells, are not subject to growth repression. Cancer cells which continue to divide and spread eventually interfere with one or more vital functions, leading to death.

The presence of cancer is characterized by at least one cellular tumor which is malignant, exhibiting either invasive or non-invasive properties. Invasive cancers are those which continue to divide and push into and invade the surrounding normal tissues. Another characteristic of cancer is metastasis, the transfer of disease from one organ to another. This process is carried out when cancerous growths shed living cells which are picked up by the blood or lymph system and carried to other parts of the body where these cells lodge, grow, divide, and invade.

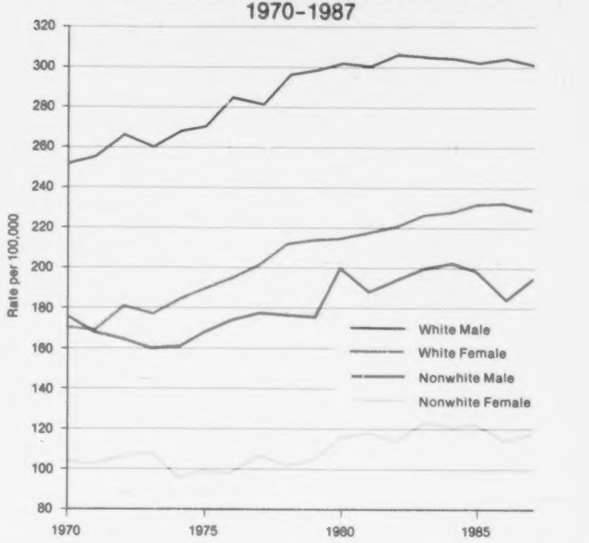
One in three Americans will develop cancer during a lifetime. Persons with cancer are likely to notice at least one of seven warning signals identified by the American Cancer Society: changes in bowel or bladder habits, a sore that does not heal, unusual bleeding or discharge, a thickening or lump in the breast or elsewhere, indigestion or difficulty in swallowing, an obvious change in a wart or mole, or a nagging cough or hoarseness.

Lifestyle, environmental, and genetic factors, individually or in combination, increase an individual's risk of developing cancer. Lifestyle factors are behaviors over which the individual has some control, such as tobacco use, diet, alcohol, sexual behavior, and excessive exposure to sunlight. Environmental factors include both occupational and medical exposure to carcinogens and exposure to naturally occurring or man-made causes of cancer that contaminate water, air, and earth. Genetic factors are conditions inherited at conception.

The total malignant cancer crude death rate increased from 42.7 per 100,000 in 1917 to 247.7 in 1987, rising by a factor of 5.8. A large percentage of this increase is due to the aging of the Florida population. Since the 1970's, the cancer death rate has generally increased among older age groups and decreased among younger age groups. This may be an indication of progress made in prolonging the life of cancer patients through more effective methods of treatment. In 1987, 71.6 percent of all cancer deaths occurred in the age group 65 years and older. The age-adjusted death rate for cancer has declined by two percent since 1970, decreasing from 127.4 per 100,000 to 124.9 in 1987.

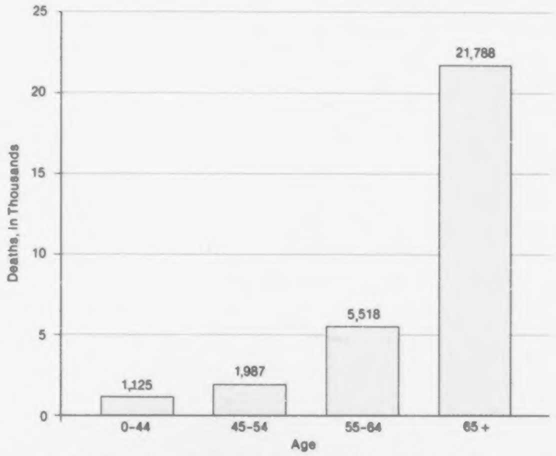
Cancer (malignant neoplasm) was responsible for 30,059 resident deaths in 1987, representing 23.7 percent of all deaths. Cancer accounted for more than three times as many deaths as the third leading cause of death (stroke). In 1987, the white cancer rate was 263.9 per 100,000 while the non-white rate was 154.7 per 100,000. All four race/sex groups showed considerable increases in crude death rates from 1970, with the largest increase occurring among white females (33.7 percent). White males had the next largest increase (19.6 percent), followed by nonwhite females (13.9 percent) and nonwhite males (10.6 percent). Despite the larger increase among white females, white males continue to have the highest cancer mortality rates.

Cancer Death Rates by Race and Sex 1970-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

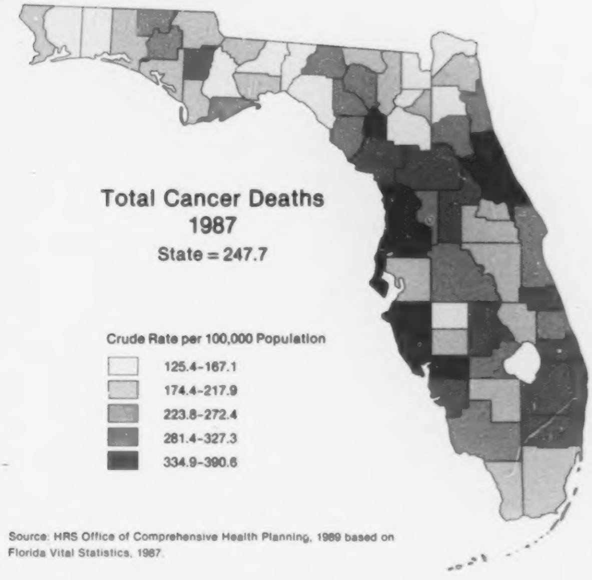
Resident Cancer Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Counties having the highest cancer crude death rates per 100,000 population in 1987 were Pasco (390.6), Sarasota (384.7), Hernando (374:7), Charlotte (374.8) and Citrus (370.3). More than 15 percent of the population in these counties are over the age of 64.

The cancers of several sites are examined in this section. Colon and rectum, lung, breast, and prostate were selected due to the larger number of 1987 Florida resident deaths attributed to cancer at these sites. Although few of the 1987 Florida resident deaths were attributed to cervical cancer, inclusion of this type of cancer is important for two reasons. First, this type of cancer is somewhat easier to detect than cancer at other sites. Second, if it is detected in an early stage, the chance of survival is higher than with other cancers.



Total Cancer Deaths
1987
State = 247.7

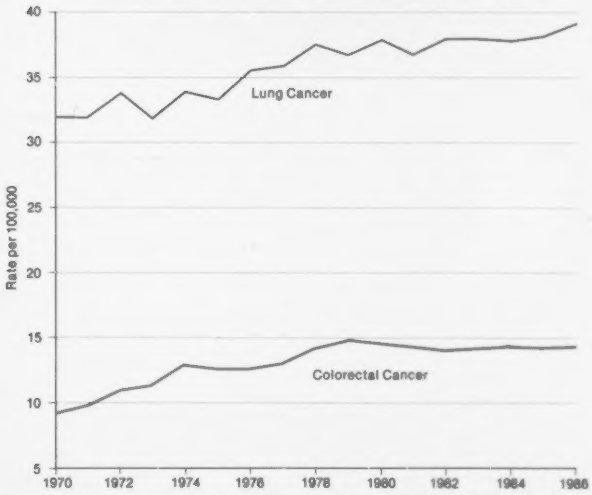
Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Colorectal Cancer

The colon, known as the large intestine, and rectum form the lower part of the digestive tract. When a tumor forms in these structures several symptoms may occur, including: the presence of blood in the stool; changes in bowel habits, such as diarrhea or constipation; and occasionally, abdominal discomfort or pain.

In total number of annual deaths, cancer of the colon and rectum is second only to lung cancer. There were 3,548 deaths in Florida from this cause in 1987. Among all race and sex groups, the incidence of colorectal cancer increased with age from 1981 to 1987. Most of the persons dying from colorectal cancer in 1987 were 65 and older. Individuals experiencing the highest incidence of colorectal cancer were white males 85 years or older. Regardless of race, males tended to experience higher incidences of colorectal cancer than females.

Age-Adjusted Death Rates for
Colorectal and Lung Cancer,1970-1986



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1986.

Florida age-adjusted death rates related to colorectal cancer between 1970 and 1986, show that the disease rates increased 52.2 percent, with an annual average increase of 3.3 percent. In 1980, these death rates peaked at 15.4 per 100,000 persons and have since declined to 14.0 per 100,000 persons, a decrease of 9.1 percent. The crude death rate has increased from 24.0 per 100,000 in 1920 to 28.4 in 1987.

Lung Cancer

Coughing, wheezing, or vague chest pains, the first symptoms of lung cancer, are such common complaints that they rarely cause a person to consult a physician. Thus lung cancer is seldom diagnosed in its early stages. Several warning signs are associated with lung cancer: a persistent cough, blood in the sputum, chest pain, and recurring pneumonia or bronchitis. However, these signs do not generally occur until the disease is well advanced.

Lung cancer was first described by doctors in the middle 1800's, however in the early 1900's this disease was still considered a rarity. The incidence of and deaths from this disease have changed drastically in the past fifty years. Lung cancer is now the leading form of cancer in Florida and the leading cause of cancer death for both men and women. The number of deaths has risen sharply since 1941, the first year in which lung cancer was recorded as a cause of death in Florida. In that year, 14 deaths were attributed to lung cancer. By 1970, 311 lung cancer deaths were recorded. Today, lung cancer exceeds automobile accidents as a cause of death. In 1987, 8,927 deaths were credited to lung cancer. Of all deaths due to cancer, 29 percent were due to cancer of the lung, trachea and bronchus.

The increase in the incidence of lung cancer has paralleled the increase in tobacco use. The higher incidence of this disease in men has been attributed to the greater prevalence of smoking among men. Between 1981 and 1985, the incidence of lung cancer in Florida was greatest among nonwhite males between 75 and 84, 531.6 cases per 100,000 persons. Among males, regardless of race, the incidence of lung cancer increased through age 84 and declined beginning with age 85.

The incidence of lung cancer among females peaked by age 74 and declined thereafter. The incidence of lung cancer among males is higher than that among females at all ages. However, the trend of increased smoking by women parallels the increase in lung cancer in women. Until 1984, breast cancer was the leading cause of cancer death in women, however, since 1985, lung cancer has been the leading cause.

In 1987, 68 percent of Floridians dying from lung cancer were 65 and older. The mortality data according to age indicates that as age increases the percentage of deaths due to lung cancer also increases. The 1987 crude death rate for all respiratory cancer was 76.2 per 100,000. This represented a 49.7 percent increase from the 1970 crude rate of 50.5 per 100,000. The 1941 crude death rate was 7.4 per 100,000.

The Florida age-adjusted death rate for lung cancer increased 21.3 percent between 1970 and 1986, a rate of 1.3 percent annually. A similar trend has also been apparent for the United States, with an overall increase of 11.6 percent between 1979 and 1986.

Breast Cancer

The most frequent site of cancer in women is the breast, even though lung cancer now kills more women than breast cancer. There are several different varieties of invasive breast cancer, as well as tiny noninvasive carcinomas. Metastasis and the spread to regional lymph nodes occurs frequently.

Women should note and discuss with a physician any changes in their breasts, such as a lump, thickening, swelling, dimpling, skin irritation, distortion, retraction or scaliness of the nipple, nipple discharge, pain or tenderness. These signs, indicating the possible presence of breast cancer, are especially likely in women over the age of 50, who either have had breast cancer previously or have a relative who has had breast cancer, who have never had children, or who have had their first child after the age of 30.

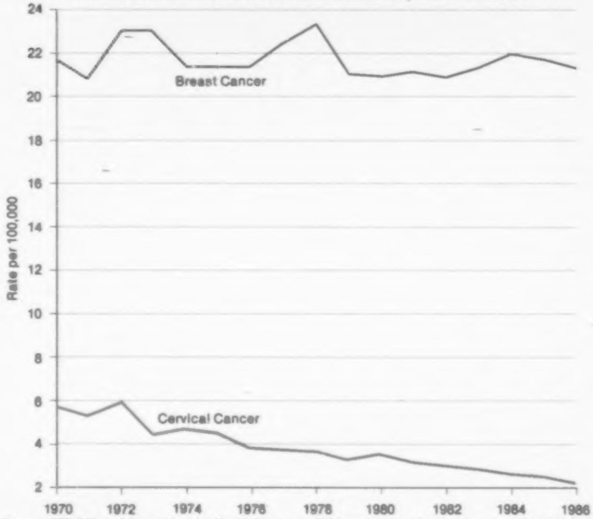
Detecting breast cancer early can be done generally through monthly breast self-examination. For this reason, the American Cancer Society recommends that all women age 20 or older practice monthly breast self-examination. In addition, it recommends that women between the ages of 20 and 40 with no apparent symptoms have a physician examine their breasts every three years. An examination by a physician is recommended every year after age 40.

In some instances, a lump may be too small to detect through breast examination. In these cases, a mammogram may be necessary to detect the lump. The American Cancer Society has recommended that all asymptomatic women between the ages of 35 and 39 should have a baseline mammogram. Beyond this, it is recommended that women between 40 and 49 should have a mammogram at least every two years and those 50 and older should have an annual mammogram.

In 1987, breast cancer accounted for 17 percent of all of the cancer-related deaths among females in Florida, with a total crude death rate of 18.6 per 100,000. The total crude rate in 1970 was 15.4 per 100,000. Sixty-one percent of the deaths due to breast cancer occurred to women 65 and older. Most of the deaths, 82.2 percent, occurred to women 55 and older. Although it is rare, breast cancer can occur in males. There were 19 male deaths due to breast cancer in 1987. However, the percentage of male deaths due to breast cancer has increased between 1970 and 1987, increasing from 0.19 percent to 0.84 percent. Many of these deaths may have been unnecessary since the probability of surviving localized breast cancer has increased to 90 percent from 78 percent in the 1940s. If a lump, or tumor in the breast, is not detected at a localized stage, it is estimated that the survival rate declines to 60 percent.

Regardless of age, whites experience higher breast cancer incidence rates than nonwhites. Among white females, the incidence of breast cancer increases with age, resulting in the highest incidence, 334 per 100,000, among those 85 years and older. Similar increases according to age were noted among the nonwhite females. The only exception was that the nonwhite incidence rate peaked between the ages of 75 and 84, resulting in a lower incidence among those 85 and older. The age-adjusted death rate for breast cancer remained relatively constant from 1970 (21.8 per 100,000 females) to 1986 (21.3 per 100,000 females).

Female Age-Adjusted Death Rates for Breast and Cervical Cancer, 1970-1986



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1986.

Cervical Cancer

The cervix is the lowest, most narrow part of the uterus. A malignant tumor in this part of the female body produces increased vaginal discharge and irregular bleeding between regular menstrual cycles, after intercourse, or after a pelvic examination. However, these symptoms are not positive signs of cervical cancer. The best means for detection is by a Pap test or smear followed by biopsy, if indicated. Cervical cancer is curable when caught in the initial early stages.

Women who were sexually active at an early age or who have had multiple sex partners are at greater risk of acquiring cancer of the cervix. The probability of survival is 80 to 90 percent when cervical cancer is diagnosed early. Disregarding the stage of the disease, the five-year survival rate is 66 percent overall, 67 percent among whites and 60 percent among nonwhites.

The incidence of cervical cancer is higher among nonwhite females than white females. Among nonwhite women, the incidence of cervical cancer increases with age, peaking at 67.8 per 100,000 females between the ages of 75 and 84. The pattern among white females, however, remains steady after age 34, with a slight peak of 21.1 per 100,000 females after age 84. After age 84, a decline in cervical cancer cases among nonwhite women results in a lower nonwhite incidence rate approaching that of white females.

Due to extensive screening programs aimed at early detection and advances in treatment, the death rate for cervical cancer has dropped more than 80 percent from 1937. Between 1970 and 1986, the Florida age-adjusted death rate has declined a total of 62.1 percent, dropping from 5.8 per 100,000 females to 2.2 per 100,000. The total crude death rate has declined from 37.0 per 100,000 in 1970 to 20.0 in 1987. The total number of deaths has remained relatively constant. There were 242 resident deaths due to cancer of the cervix in 1987. Fifty-seven percent of the deaths due to cervical cancer occurred in women less than 65 years old.

Prostatic Cancer

The prostate is one of the fluid-producing glands in the male reproductive system. It is located just below the urinary bladder. The urethra, which carries urine from the bladder, passes through it. A malignant tumor around the prostate can result in back pain, painful urination or painful ejaculation. Also, urinating may be difficult and the urine may contain blood or pus. These symptoms, however, need not be present with prostatic cancer.

Before 1900, prostate cancer was considered a rare disorder. Today it is second only to lung cancer as the most frequent cancer among men. It is the third leading cause of cancer deaths in males behind lung cancer and colorectal cancer. This is due in large part to the increasing number of men who are living longer than at the turn of the century.

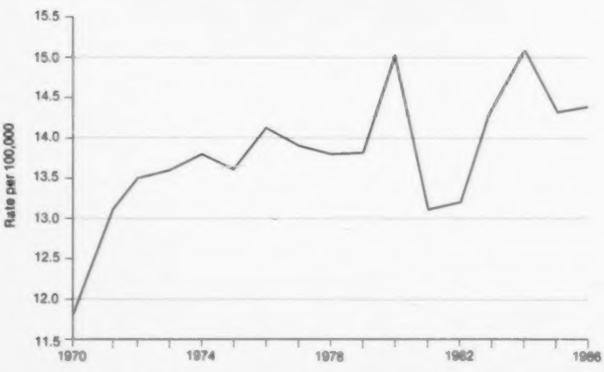
Since 1950, the incidence of prostate cancer has increased steadily, but mortality has shown only a minimal increase over the same period except in men 85 years and older. This pattern is most likely a result of the detection of increased numbers of cases of the disease; diagnosis at earlier stages of the disease; and more successful therapy for the disease.

Prostate cancer occurs in men most often after the age of 40 and increases in incidence with age more rapidly than any other cancer. Among white men, this type of cancer increases with age, resulting in the highest incidence rate after age 84, 1,001 cases per 100,000 males. Nonwhite males experience higher rates than whites and the incidence rate tends to peak at an earlier age, 1,042 cases per 100,000 males between the ages of 75 and 84.

The American Cancer Society has reported that the incidence of prostatic cancer among black Americans is the highest in the world, although the reason is not known. Family history, dietary fat intake, and occupational exposure to cadmium appear to be predisposing factors related to cancer of the prostate.

The number of deaths due to prostate cancer has increased greatly over the past forty years. In 1947, there were 175 resident deaths; in 1967, there were 645; and in 1987 there were 1,983. The majority of deaths due to prostatic cancer in 1987, 91.2 percent, occurred to men over 64. The age-adjusted death rate per 100,000 males was 14.4 in 1986, an increase of 22 percent from the 1970 rate of 11.8 per 100,000 males.

Age-Adjusted Male Death Rates for Prostatic Cancer, 1970-1986



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1986.

Chronic Obstructive Lung Disease

Chronic Obstructive Lung Disease and Allied Conditions (COLD) includes bronchitis, emphysema, asthma, bronchiectasis, extrinsic allergic alveolitis and chronic airways obstruction. Aside from chronic airways obstruction, emphysema results in the greatest number of deaths in this grouping.

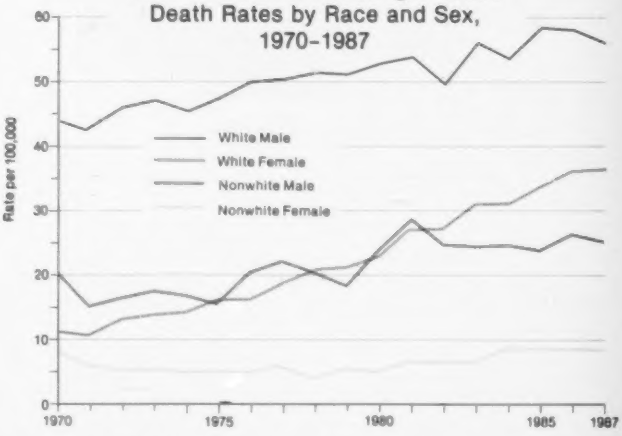
With emphysema the alveoli, air sacs of the lung, lose their elasticity, overexpand, and may rupture forming cysts. When this occurs, carbon dioxide cannot be completely expelled and accumulates in the lungs, and breathing is difficult. The main symptom of emphysema is shortness of breath, which gradually worsens over a period of years. Emphysema usually occurs in people who have bronchitis or asthma. It is much more common in men than in women and risk of acquiring the disease increases if a person smokes and/or lives in an area where the air is polluted.

Symptoms associated with other types of COLD vary. Bronchitis is the persistent inflammation of one or more bronchi. Persons with chronic bronchitis are likely to experience a chronic cough, due to excessive production of mucus in the bronchi, and by the production of sputum.

Asthma is a chronic condition characterized by periodic attacks of wheezing and difficulty in breathing. The cause of asthma attacks is partial obstruction of the bronchi and bronchioles because of the contraction of the muscles in the bronchial walls. Persons with asthma have a trachea and bronchi which are overly sensitive and exhibit allergic reactions by constricting and reducing the ability to breathe. Most asthma is triggered by an allergy to such things as pollen, animal hairs, and small mites in house dust.

White males continue to have significantly higher crude death rates than the other race/sex groups (55.7 per 100,000), more than double the rate for nonwhite males (24.9 per 100,000). Nonwhite males were the second highest group until 1981, when white females took over that ranking and have maintained it ever since. The white female crude death rate in 1987 was 36.1 per 100,000. The percentage of white female deaths has increased from twenty percent of the deaths in 1970, to nearly forty percent in 1987.

Chronic Obstructive Lung Disease Death Rates by Race and Sex, 1970-1987

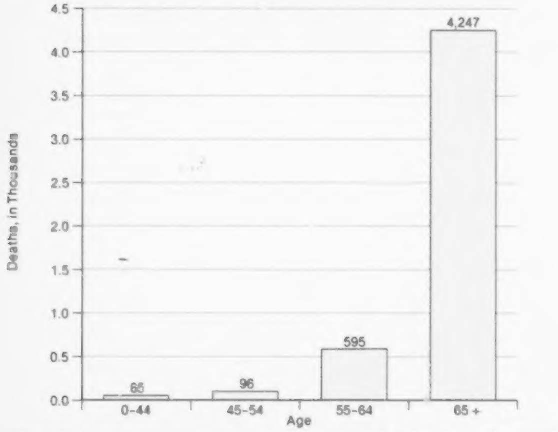


Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

The age-adjusted death rates due to COLD have increased in both Florida and the United States. The annual average percentage increase, however, has been greater in the United States, 4.1 percent per year, than in Florida, 1.0 percent per year. Florida's 1987 age-adjusted death rate was 17.0 per 100,000 compared to 14.8 per 100,000 in 1970.

Residents 65 and older experienced the highest percentage, 84.9 percent, of all deaths due to COLD and whites accounted for 94 percent of the COLD deaths. The crude death rate for whites was 45.6 per 100,000 and for nonwhites 16.3 per 100,000.

Resident Chronic Obstructive Lung Disease Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Florida's total crude death rate was 41.2 per 100,000 in 1987. Counties experiencing the highest crude death rate per 100,000 population for COLD were Calhoun (123.2), Franklin (81.7) and Citrus (77.2). Union County had the lowest rate with 9.3 per 100,000.

Cirrhosis

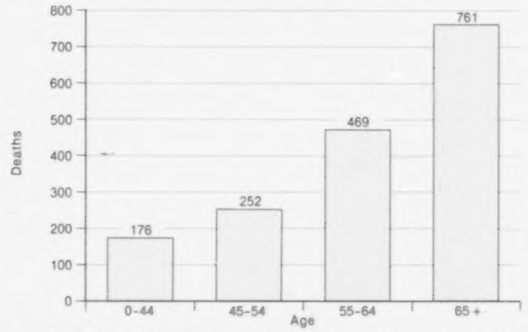
Cirrhosis of the liver consists of several diseases which are noted for inflammation and formation of fibroid structures. These diseases result in structural changes within the liver and ultimately lead to loss of function. The liver is a major excretory organ which removes substances from the blood. The most common type of cirrhosis in North America is Laennec's cirrhosis. This type is precipitated by alcoholism and nutritional deficiencies resulting from pancreatitis, diabetes mellitus, and ulcers in the colon. As cirrhosis progresses, massive collagen formations appear which in later stages reduce the size and appearance of the liver.

Symptoms associated with cirrhosis do not occur for several years until the disease is more advanced. When the first symptoms appear they may include lassitude, anorexia, dyspepsia, flatulence, a change in bowel habits, slight weight loss, and nausea or vomiting in the morning. In later stages, jaundice, fluid accumulation in the peripheral portions of the body, bleeding tendencies, redness of the palms of the hands, the appearance of spider-like patterns on the skin, and a musty sweet odor on the breath are noticed. The final stage of the disease occurs with hepatic coma.

Once an individual has cirrhosis of the liver little can be done. The best which can be achieved is prevention of further damage and supportive care for the patient. Therefore, the key to curtailing cirrhosis is limiting alcohol intake to prevent the onset of the disease. Cirrhosis is positively correlated with the duration and amount of alcohol consumption. According to 1987 Florida mortality data, 33 percent of the cirrhosis deaths were alcohol related.

In 1987, most of the deaths due to cirrhosis, 57.6 percent, were to persons between the ages of 45 and 65. Whites experienced higher race-specific death rates of 14.5 per 100,000 compared to 9.2 per 100,000 for nonwhites. Florida's total crude death rate was 13.7 per 100,000. Counties having the highest cirrhosis crude death rates per 100,000 in 1987 were Glades (27.0), Walton (25.2), and Charlotte (25.7). Six counties in northern Florida reported no deaths from cirrhosis in 1987.

Resident Cirrhosis Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

The percentage of cirrhosis deaths for males has been higher than that of females. In 1987, 64 percent of all cirrhosis deaths were males. The white and nonwhite male crude death rates were 19.2 per 100,000 and 11.6 per 100,000, respectively. Comparatively, the white and nonwhite female rates were 10.0 per 100,000 and 7.0 per 100,000, respectively.

The age-adjusted death rates for cirrhosis have declined faster in Florida, 32.9 percent, than in the United States, 14.3 percent. In 1973, Florida experienced peaks in the age-adjusted death rates due to this cause, with a rate of 17.5 per 100,000 persons. The Florida rate has continued to decline since then. The 1987 rate was 9.3 per 100,000 population.

Diabetes Mellitus

Diabetes mellitus, or simply diabetes, is a common disorder which occurs when the pancreas either totally stops producing insulin (which regulates carbohydrate, lipid, and amino acid metabolism), or does not produce enough of the hormone for the body's needs. This results in a low absorption of glucose, both by the cells, which need it for energy, and by the liver, which stores it. Thus the body is unable to properly use or store carbohydrates, fats, and proteins.

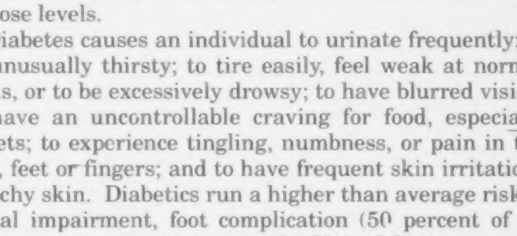
Two different types of diabetes are recognized by the National Diabetes Data Group: insulin-dependent diabetes, also known as Type I diabetes, and noninsulin-dependent diabetes, referred to as Type II diabetes. Persons with Type I diabetes are partially or completely unable to produce insulin. Without daily insulin injections they would die. This form of diabetes occurs mainly in young people.

Type II diabetes, which is associated with obesity and usually affects people over 40, is more prevalent. Heredity is also an important factor, in many of the cases there is a family history of the disease. Persons with Type II diabetes are able to control their blood glucose levels with diet, exercise, and/or oral medications since the pancreas does function, however, the amount of insulin produced is inadequate for the body's needs. Some persons with Type II diabetes require insulin injections due to their unwillingness to modify their lifestyles to control their blood glucose levels.

Diabetes causes an individual to urinate frequently; to be unusually thirsty; to tire easily, feel weak at normal tasks, or to be excessively drowsy; to have blurred vision; to have an uncontrollable craving for food, especially sweets; to experience tingling, numbness, or pain in the legs, feet or fingers; and to have frequent skin irritations or itchy skin. Diabetics run a higher than average risk of visual impairment, foot complication (50 percent of all nontraumatic amputations in the United States occur in people with diabetes), kidney complications, acute hyperglycemia and ketoacidosis, and adverse outcomes in pregnancy.

Mortality from diabetes has always been associated with aging, but diabetics are increasingly able to live longer and more productive lives than in earlier years. In 1950, 10.3 percent of all diabetes deaths occurred to those under 45 years of age compared to only 4.9 percent in 1987. In the 45-64 age group the percentages were 36.8 percent in 1950 to 18.8 percent in 1987. Persons 65 and older accounted for 53 percent of the 1950 deaths but in 1987 they accounted for 76.2 percent all deaths from diabetes.

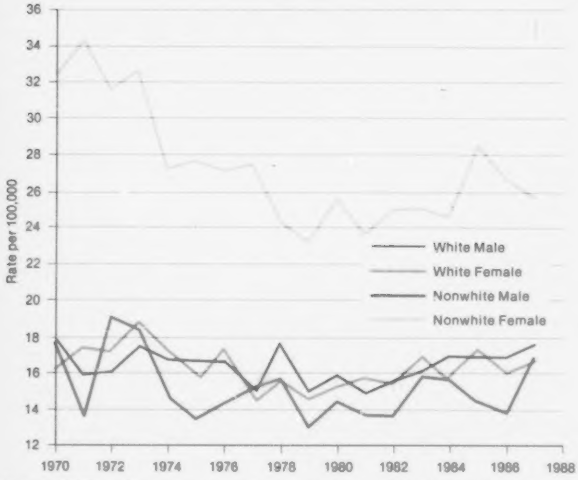
Resident Diabetes Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Nonwhites experienced higher race-specific death rates than whites (21.6 per 100,000 compared to 17.0). Diabetes is a major problem in Florida for nonwhite females. Nonwhite females had a crude death rate of 25.8 per 100,000 which was one and a half times greater than the other three race/sex segments. White and nonwhite males had about the same diabetes death rate, 17.8 and 17.0, respectively. White females had the lowest rate of 16.3 per 100,000. The age-adjusted death rate related to diabetes declined 23 percent from 10.9 per 100,000 in 1970 to 8.4 in 1987.

Diabetes Death Rates by Race and Sex, 1970-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

In 1987, diabetes resulted in 2,150 deaths for a total crude rate of 17.7 per 100,000. Counties having the highest crude rate per 100,000 population were Gilchrist (98.2), Levy (45.8) and Taylor (42.4). Six north Florida counties reported no deaths from diabetes in 1987.

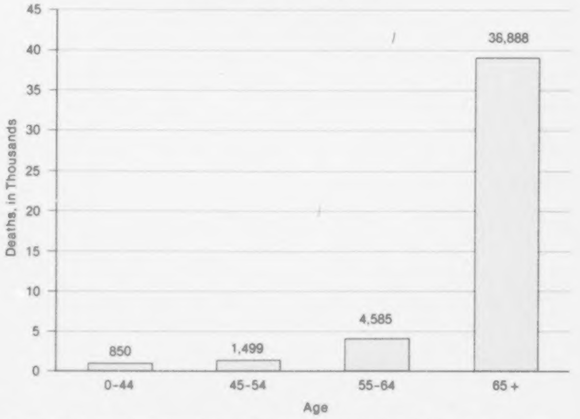
Heart Disease

The specific diseases falling under the general classification of heart disease include: rheumatic fever; hypertensive heart disease, pericarditis (inflammation of the pericardium, the fibroserous sac that surrounds the heart and the roots of the large vessels); endocarditis (inflammation of the endocardium and generally associated with rheumatic fever and other acute febrile diseases); myocarditis (inflammation of the muscular walls of the heart); dysrhythmias (abnormal heart beat rhythm); ischemic heart disease (a deficiency of blood supply to the heart muscle due to an obstruction or constriction of the coronary arteries); and heart failure (most often applied to myocardial failure and resulting in cardiac output inadequate for the body's needs). Some of the symptoms of heart disease include chest pain; difficulty in breathing; palpitations (an awareness of the heartbeat due to changes in the heart rate); swelling; transient loss of consciousness, fatigue, and weakness. A heart attack (myocardial infarction) occurs when the heart receives an insufficient supply of blood. The heart is starved of oxygen and nutrients and a portion of the muscle dies.

Heart disease became the leading cause of death in Florida in 1921 and has retained that rank ever since. By 1940, the heart disease death rate had doubled and by 1970 had more than tripled to 391.1 per 100,000 population. Since then, the rate has been relatively stable and by 1987 had actually decreased by 3.5 percent to 377.6 per 100,000. This decrease is thought to be a result of an increase in coronary care units, coronary artery bypass surgery, medical therapy, reductions in blood pressure, reductions in serum cholesterol, smoking cessation, increased exercise, and weight loss. Heart disease accounted for the deaths of 45,822 Floridians in 1987, accounting for 36.1 percent of total deaths from all causes, or more than a third. Deaths from heart disease exceeded cancer deaths by 1.5 and stroke deaths by 5.1.

Heart disease, like other chronic diseases, is associated with aging. In 1987, the largest percentage of Florida deaths due to heart disease occurred among persons 65 years of age or older (85.4 percent), while people under 45 accounted for less than two percent.

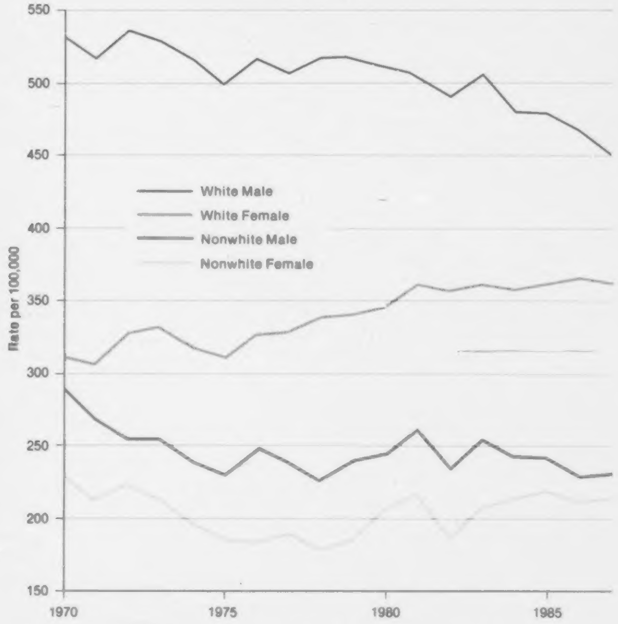
Resident Heart Disease Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987

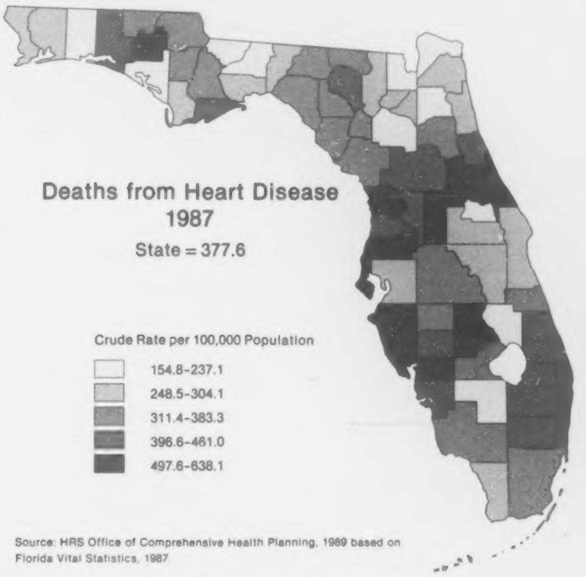
The percentage of deaths among whites is greater than among nonwhites. In 1987, the crude death rate for whites was 404.9 per 100,000 while the nonwhite rate was 233.1. Florida's 1987 total crude death rate for heart diseases was 377.6 per 100,000.

Heart Disease Deaths by Race and Sex, 1970-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

Counties with the highest crude death rates were Citrus (638.1), Charlotte (591.8), Pinellas (585.7), and Pasco (554.8). Leon County had the lowest rate with 154.8 per 100,000. HRS Districts five, ten, and eight had the highest crude death rates with 578.4, 455.6, and 445.9, respectively.



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Between 1970 and 1987, the trends regarding heart disease deaths according to sex have changed. In 1970, the percentage difference between the male and female mortality experience was 54.6 percent with males experiencing the greater number of deaths. By 1987, however, the percentage difference had declined to 20.0 percent. This change in the percentage difference is attributable to both a decrease in heart disease deaths among males and an increase among females.

The heart disease age-adjusted death rates have declined an average of 2.6 percent each year since 1970, resulting in a total decline of 30.0 percent. The 1970 age-adjusted rate was 217.8 per 100,000 and the 1987 rate was 152.9.

Heart Disease Age-Adjusted Death Rate, 1970-1987

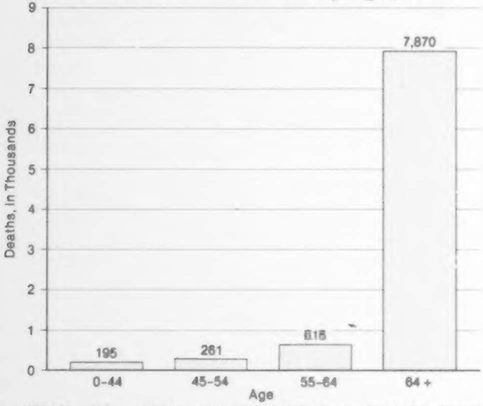
Stroke

The medical term for stroke is cerebral vascular accident, meaning that the arteries to the brain or within the brain have suffered an accident preventing blood from reaching a portion of the brain. There are a number of terms used for stroke including cerebrovascular disease, a general term used to cover a wide variety of conditions, and cerebral hemorrhage, a bleeding into the brain due to the rupturing of either a blood vessel or an aneurysm. Most strokes result from rupture of vessels or from blood clots forming in the blood vessels. When a part of the brain goes without blood for more than four to ten minutes, that part of the brain dies. However, brain tissue cannot regenerate like most other body tissue.

The results of a stroke range from minor damage to rapid death depending on the size and location of the affected area. Speech impediments, some degree of paralysis, loss of memory or other mental function, and blindness are consequences that can result from stroke. Risk factors associated with stroke include smoking, high blood pressure, increased cholesterol, a high fat-low fiber diet, high sodium intake, obesity, lack of exercise, stress, diabetes, and cardiac impairment.

In 1987, 8,942 deaths were reported in Florida as a result of stroke. Most deaths occurred among persons 65 years of age or older (88 percent). Stroke is the third leading cause of death for persons 45 and older. Blacks are more likely to die from stroke at 45-54 years of age than are whites. This racial difference is related to the higher blood pressure levels found among the black population. High blood pressure increases the risk of stroke by promoting the narrowing of the arteries with fatty deposits and by contributing to the rupture of fragile brain vessels.

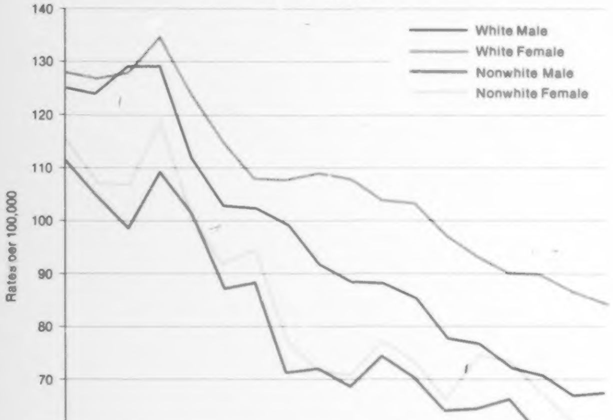
Resident Stroke Deaths by Age, 1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1987.

Stroke causes more deaths among females than males and among more whites than nonwhites. White females have had the highest crude death rates of all race/sex groups since 1970. However, the white female rate has declined from 127.0 per 100,000 in 1970 to 84.5 in 1987. All other race/sex groups have also shown similar declines. White male rates have declined from 124.7 per 100,000 in 1970 to 67.5 in 1987, non-white female rates have declined from 114.5 to 60.9, and non-white male rates have declined from 110.9 to 55.6 in 1987.

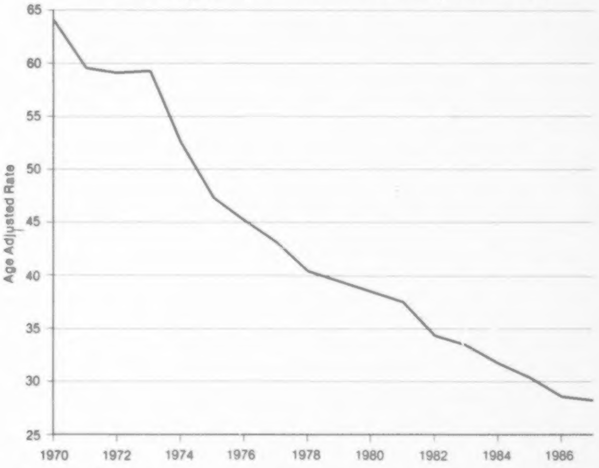
Stroke Death Rates by Age and Sex, 1970-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

Crude death rates have declined more than 40 percent in the past two decades, showing a steady decline regardless of race or sex. In 1970, the total crude death rate was 124.0 per 100,000 and in 1987 it was 73.7 per 100,000. The 1987 age-adjusted death rate was 28.1 per 100,000, a 56 percent decrease from the 1970 rate of 64.0 per 100,000. This trend continues despite the fact that Florida's population has continued to age. Reasons for this decline appear to be because of preventative measures such as high blood pressure detection and control, reduction of smoking, better diets, increased exercise and fitness, and better stress management.

Stroke Age-Adjusted Death Rate, 1970-1987



Source: HRS Office of Comprehensive Health Planning, 1989 based on Florida Vital Statistics, 1970-1987.

Counties with the highest crude death rates per 100,000 population in 1987 were Sarasota (139.8), Pinellas (132.1), Highlands (129.4), Sumter (128.7) and Citrus (121.8). Liberty County had the lowest rate with 20 per 100,000.

Communicable Diseases

Communicable diseases are diseases caused by a specific infectious agent or its toxic products through a direct or indirect mode of transmission of that agent from a reservoir. A reservoir is the environment in which an infectious agent lives and multiplies and on which it depends for survival. Man is the most frequent reservoir of infections that are capable of producing disease in other humans. Thus the most obvious means of transmission of infection is directly from person to person, e.g., by coughing, sneezing, kissing, etc. These diseases have been grouped into two classes in the atlas: (1) childhood and other immunizable diseases and (2) sexually transmitted diseases.

Infectious agents are also transmitted indirectly in a variety of ways. Infected individuals shed infectious agents into the environment. These are deposited on a variety of surfaces and can be resuspended in air, at a later time. As a result, infection is spread indirectly to other hosts. Similarly, infectious agents can get into the soil, the water, the food, or other chains of indirect transmission. Infections can also be spread via exudates and excreta. Blood transfusions may also be a means of spreading infection, as in the case of AIDS or viral hepatitis. More complex types of indirect transmission involve vectors such as insects. These diseases have been grouped into four classes: (1) food-borne diseases, (2)water-borne diseases, (3) air-borne diseases and (4) zoonotic diseases.

Public health efforts have been very succesful in combatting communicable diseases. As a result, Florida morbidity rates in the 1980s are substantially different than they were a hundred years ago. Some of these diseases have been totally eradicated and others now occur relatively infrequently. These diseases are discussed in the following section on historical disease trends rather than in the six classes identified above.

Historical Disease Trends

During the early years of Florida's development, communicable diseases were a substantial impediment to settlement. In the nineteenth century, Floridians faced major communicable disease threats from mosquito-borne diseases of the tropics (denque fever, malaria and yellow fever); water-borne diseases (cholera and typhoid fever); and smallpox. Epidemics of each of these diseases occurred throughout the late nineteenth and early twentieth centuries, especially since Florida's warm climate enabled the spread of disease organisms imported through Florida's many ports. As knowledge of the causes of these diseases increased, public health officials developed improved sanitation practices, mosquito control programs and a maritime quarantine system which resulted in substantial reductions in the incidence of most of these diseases. Yellow fever, epidemics of which decimated Florida's ports between 1860 and 1900, has been substantially eliminated. Immunization programs have eradicated smallpox worldwide with the last case reported ten years ago. However, some of these diseases are still found in Florida.

Cholera

Cholera is an acute intestinal disease which is caused by the bacterium *Vibrio cholerae*. It is characterized by diarrhea, vomiting, rapid dehydration and circulatory collapse. Death may occur within a few hours of onset. Transmission mainly occurs through ingestion of water contaminated with infected persons' feces, although there is some indication that the disease may be transmitted through ingestion of raw oysters. According to the Florida Audubon Society, cholera pathogens are chronically present in some of Florida's estuarine environments and thus may infect seafood harvested from these areas. Although cholera epidemics occurred in Florida in the late nineteenth century, there have been few cases reported since the start of detailed morbidity reporting in 1918. There was one case of cholera reported in each of the years 1982, 1985, and 1986. Prior to these dates the last case reported in Florida was in 1937.

Dengue Fever

Dengue viruses are endemic in many of the islands of the Caribbean and several Central and South American countries. Dengue fever is an acute febrile disease characterized by sudden onset, fever for about five days, joint and muscle pains, and a rash appearing three to four days after onset of fever. Transmission is by the bite of infective mosquitoes. Cases of dengue fever have been recorded in Florida since 1918. Epidemics occurred in Florida in 1922 and 1934 when 4,988 cases and 2,015 cases respectively were reported. In the past 20 years, a total of 31 cases have been reported with 13 of those reported in 1981. In 1987, two cases were reported for a case rate of 0.02 per 100,000 population. No occurrences were reported in 1988.

Malaria

-Malignant tertian malaria is the most serious of four human malarias. It is characterized by fever, chills and sweating, headache, coagulation defects, shock, renal failure, acute encephalitis and coma. Case fatality exceeds 10 percent among untreated children and nonimmune adults. The other human malarias, benign tertian, quartan and ovale, generally are not life threatening except in the very young or in patients with concurrent disease. These are characterized by a shaking chill and rapidly rising temperature, usually accompanied by headache and nausea and ending with profuse sweating. Relapses are common and may occur at irregular intervals for several years. Malaria is transmitted by the bite of an infective female anopheline mosquito which remains infective for life. Transmission may also be by injection or transfusion of blood of infected persons or by use of contaminated needles, as by drug addicts. Congenital transmission may also occur.

Malaria cases have been recorded in Florida since 1918. Malaria reached epidemic proportions in 1919, 1923-24, 1929, and 1934-35. Mosquito control programs have greatly reduced the threat of malaria. Over the past 20 years, the number of new cases reported has remained fairly constant while the case rate per 100,000 population has decreased slightly due to population increases. In 1969, 54 cases were reported for a case rate of 1.06 per 100,000; in 1971, 39 cases occurred with a case rate of 0.5 per 100,000. In both 1987 and 1988, 39 cases were also reported with a case rate of 0.3 per 100,000 for both years. In 1988, 44 percent of the cases (17 cases) were reported in Dade County and 12.8 percent of the cases (5 cases) were reported in Broward County.

Typhoid Fever

Typhoid fever is a systemic bacterial disease characterized by sustained fever, headache, malaise, anorexia, constipation and rose spots on the trunk of the body. The typhoid bacterium can be transmitted by food or water contaminated by feces or urine of a patient or carrier. Shellfish taken from sewage-contaminated beds, raw fruits, vegetables, milk and milk products contaminated by the hands of carriers are some vehicles for transmission.

Cases of typhoid fever have been recorded in Florida since 1918 and have steadily declined in both numbers and case rate since then. Sixteen cases of typhoid fever were reported in Florida in 1987, a case rate of only 0.1 per 100,000 persons and in 1988, 19 cases were reported, a case rate of 0.2 per 100,000.

Communicable Disease Risks

A listing of communicable diseases of importance to Floridians is included on the following pages. The listing includes the environmental, behavioral and other risk factors which increase the possibility of contracting each of these diseases. Incidence data is also included to show the comparative risks of contracting these diseases in 1980 and 1988. However, some diseases are not reportable, thus comparative risk data is not available for all diseases.

Childhood/Immunizable Diseases

Infectious diseases are prevalent during early childhood when resistance to infectious agents may still be low but exposure is beginning to increase as a result of social involvement outside the home. The incidence of communicable diseases of childhood has declined tremendously since the introduction of immunizations. Over the past 25 years, mass vaccination programs have resulted in 98 percent declines in the incidence of measles, mumps, rubella, pertussis, diphtheria, and polio. Serious complications resulting from these infections have also been reduced with the use of antibiotics and antitoxins. Communicable diseases no longer result in high death rates for children. Smallpox, which was a major health problem in Florida in the late nineteenth century, was eliminated worldwide by 1977 through mass immunization programs, but the causal agents for the other major diseases of childhood have yet to be eliminated.

Epidemics of the childhood infectious diseases could recur if immunity levels within the population are not maintained. Most immunization programs are intended to control the spread of communicable diseases to which children are particularly susceptible. These diseases do occur in adults, but historically they have been most common among children. Most children spend many hours in schools, day care centers and other areas where proximity to numerous other children presents an opportunity for rapid spread of disease organisms. Florida law currently mandates that all children entering a public school or preschool receive immunizations for diphtheria, mumps, pertussis, poliomyelitis, rubella, rubeola, and tetanus. Haemophilus influenza B is an optional immunization. Florida's public universities also require rubeola and rubella immunizations for students within the State University System.

Chickenpox

Chickenpox is an acute generalized viral, non-immunizable, disease characterized by sudden onset with slight fever and malaise followed by the eruption of multiple small erythematous macules, papules, and vesicles. The virus which causes chickenpox is a DNA herpes virus. The disease is highly contagious when active. The incubation period is 14 to 21 days. Infection usually occurs in school-age children but occasionally affects young adults. The eruptions become purulent and crusted and heal spontaneously usually within one week. The lesions initially appear on the trunk and face and spread peripherally to the extremities.

In metropolitan communities, about three fourths of the population have had chickenpox by age 15. Susceptibility is universal among those not previously infected. One infection confers long-term immunity and second attacks are rare. However, infection can remain latent and may recur years later as herpes zoster in a proportion of older adults and sometimes in children. Chickenpox is ordinarily a more severe disease in adults. Both adults and immunosuppressed children may also develop pneumonitis or encephalitis after contracting chickenpox, both of which can be fatal. In Florida, chickenpox occurs most frequently in winter and early spring. Chickenpox has not been a reportable disease in Florida since 1978.

Diphtheria

Diphtheria is an acute bacterial disease which primarily affects the nose and throat causing lesions, inflammation and swelling. Severe cases may result in nerve palsies, myocarditis, and death in 5-10 percent of cases. Transmission is by direct contact with an infected person. The disease is most common during the colder months and among unimmunized children under age 15. Although diphtheria was one of Florida's major health problems in the late nineteenth century and caused a sizeable number of deaths as late as 1926, it has now been substantially eliminated. Today deaths from diptheria are almost unknown, largely because of the mass immunization of infants. The diphtheria vaccine was licensed in 1949. As a result of the compulsory immunization program, only one case (in 1981) has been reported in Florida since 1973. The progress and success of immunization as a preventive medical tool is vividly illustrated in the history of this disease.

Haemophilus Influenza Type B

Haemophilus influenza type B is an acute infectious bacterial disease of the respiratory tract which produces flu-like symptoms. It accounts for about 400 cases of bacterial meningitis annually in Florida with a case fatality rate of 3.4 percent. Over 90 percent of the victims are under age 5. Recent studies show that the risk of acquiring primary haemophilus influenza B for children under 5 appears to be greater for those who attend day care facilities than others.

The Immunization Practices Advisory Committee of the Public Health Service (ACIP) recommends that all children be immunized with HIB (Haemophilus influenza B) vaccine at 18 months of age. The ACIP also recommends that children between the ages of 3 and 4 be immunized, but the decision to immunize should be based on risk of disease.

Mumps

Mumps is an acute, rarely fatal, viral disease affecting the salivary glands. Transmission is by person to person; one-third of exposed susceptible persons have no clinical manifestations, and one attack. clinical or subclinical, confers long-term immunity. Adult immunization is advisable because mumps can cause serious secondary problems after puberty. Immunization after 1 year of age with live attenuated vaccine confers lifelong protection.

In 1987, 67 cases of mumps were reported. Children aged 5-9 had the highest incidence (3.8 per 100,000) with 28 cases. Ten cases were reported in the 1-4 year-old group. In 1988, 43 cases (0.03 per 100,000) of mumps were reported with both Palm Beach County and Polk County reporting nine cases each. This represents a 35.8 percent decrease from the number of cases reported during 1987. Mumps cases declined after the introduction of live mumps virus vaccine in 1968 and after the recommendation for its routine use in 1977.

Mumps Case Rates 1918-1988

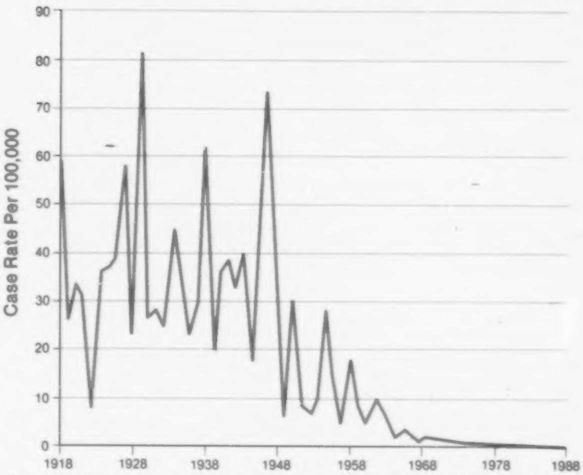
Pertussis (Whooping Cough)

Pertussis is an acute bacterial infection of the trachea and bronchus, usually affecting very young children. It is highly lethal in unimmunized populations, but one attack confers long-term immunity. Vaccinations, licensed in 1914, have greatly reduced pertussis morbidity.

In 1987, 53 cases of pertussis were reported in Florida, an incidence rate of 0.4 per 100,000. Children less than 1 year of age had the highest occurrence, 27 cases (216.0 per 100,000) followed by 1-4 year olds, 17 cases (2.1 per 100,000). In 1988, 72 cases (0.6 per 100,000) were reported with Dade County reporting 36 percent of these cases.

Pertussis Case Rates 1918-1988



Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1918-1988.

Poliomyelitis

Poliomyelitis or polio, is an acute viral infection with symptoms that include fever, headaches, nausea, vomiting, excessive muscle pain and spasms, and stiffness in the back and neck. Severe cases may result in aseptic meningitis, paralysis and death. Although the virus can be transmitted via feces, the most common transmission is through direct contact, usually via inhalation of airborne droplets. Polio characteristically is a disease of children and adolescents, but when adults are infected, the disease frequently is more severe, with increased risks of paralysis and death.

Polio cases have been recorded in Florida since 1923. A major outbreak occurred in Florida during 1953 when a total of 1,777 cases were reported. Since the development of polio vaccines (injections 1955 and oral 1967), few cases have been reported. These cases usually are limited to members of religious groups who are doctrinally opposed to immunization and to unimmunized preschool children from poor families. However, Florida has reported three cases since 1985. A total of six cases have been reported since 1965. There were no cases reported during 1987 or 1988.

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1918-1988.

Rubella or German Measles

Rubella is a viral disease characterized by a mild fever, malaise, and often a rash. The disease occurs two to three weeks after exposure and lasts about a week. Congenital Rubella Syndrome occurs among 20-25 percent or more of infants born to women who have acquired rubella during the first trimester of pregnancy, with decreasing frequency thereafter. The syndrome often results in various birth defects and retardation for the infant, and may be fatal.

Ten cases of rubella were reported in Florida in 1987. Children ages 1-4 had the highest incidence with nine reported cases. In 1988, three cases (0.02 per 100,000) were reported in Florida, the lowest recorded since 1936. The incidence of rubella has declined by more than 99 percent since 1969, the year rubella vaccine was licensed. The case rate has been declining steadily and no case of Congenital Rubella Syndrome has been reported since 1981.

Rubeola (Measles)

Rubeola is an acute, highly communicable viral disease characterized by fever, conjunctivitis, and bronchitis. A red blotchy rash appears on the third to seventh day, becoming generalized, and lasting four to six days. Transmission is by droplet spread or direct contact with nasal or throat secretions of infected persons. The incubation period is about 10 days from exposure to the onset of fever, with the rash appearing about four days later. The disease is communicable from the time of fever to four days after the appearance of the rash.

All unimmunized persons are susceptible. Permanent acquired immunity is usual after an attack and infants born of mothers who have had the disease (not during pregnancy) are ordinarily immune for approximately the first six months of life. A single vaccination induces active immunity in more than 95 percent of susceptible children, usually for life. Pregnant women contracting the disease, especially during the first trimester, put the fetus at risk for developing congenital anomalies. Possible adverse affects in young children include an inflammation of the brain, which can lead to deafness or mental retardation.

The Florida case rate trend for measles shows major outbreaks during the 1940's and the 1950's. The last major outbreak occurred during 1958, when 12,514 cases were reported. Since 1963, the incidence of measles decreased by 99 percent and the disease was thought to be headed for eradication until the case count increased in 1986.

There were five outbreaks in Florida during 1986: 65.5 percent of the total cases (262 cases) were reported in Dade County and 20 percent of the total cases (81 cases) were reported in Orange County. Statewide, children ages 1-4 (215 cases) had the highest incidence of illness (35.3 per 100,000). The 15-19 age group had 84 cases (10.8 per 100,000) followed by the 5-9 age group with 38 cases (5.5 per 100,000). In 1987, Florida had 126 reported cases of rubeola; a case rate of 1.0 per 100,000. In 1988, there were 170 cases of rubeola reported for a case rate of 1.4 per 100,000 population. Of these cases, 44 percent were reported in Orange County (75 cases) and 21 percent were reported in Dade County (35 cases).

Tetanus

Tetanus or lockjaw is an acute disease resulting from a toxin produced by the anaerobic tetanus bacillus, which grows at the site of an injury, usually a puncture wound, contaminated by the bacillus. There is no direct transmission. Symptoms include muscular contractions and spasms, especially of the jaw and neck muscles, and abdominal rigidity. Fatality rates run between 30 and 90 percent depending upon patient age, length of incubation and therapy.

Since the advent of immunizations for tetanus the incidence has declined substantially, with only four cases reported in Florida in 1987 and four cases in 1988. In addition to the DTP vaccine included as part of the recommended childhood immunization schedule, tetanus vaccinations are also available as diphtheria/tetanus (DT) for children under age 7 and tetanus and diphtheria toxoid (Td) for adults. Booster shots are recommended at 10-year intervals.

Sexually Transmitted Diseases

Sexually transmitted diseases (STDs) are contagious diseases spread almost exclusively from one person to another by heterosexual or homosexual intercourse or intimate contact. Since the causative organisms survive only very briefly outside a warm, moist environment, there is almost no way to contract STDs from toilet seats, towels, or bed linens.

There are some notable exceptions to sexual transmission. During pregnancy the fetus may become infected in utero by placental transmission, and the infant may acquire congenital syphilis or be stillborn. Infants of mothers with gonorrhea may contract eye infections during birth and, unless treated, this can lead to permanent blindness.

The actual incidence of STDs is unknown because many cases are not reported by the clinicians who treat them and because of variable reporting requirements. All states require that each case of syphilis, gonorrhea and acquired immune deficiency syndrome (AIDS) be reported to the state or local health office. All other STDs are reportable in only some states and some, such as herpes genitalis, are not reportable in any states. However, it is known that the STD problem is growing at an alarming rate.

Syphilis, gonorrhea, chancroid, lymphogranuloma venereum, and granuloma inguinale are the five classic venereal diseases, but AIDS is the disease which has captured public attention recently. State programs aimed at controlling gonorrhea and syphilis existed for decades, while programs aimed at other STDs are relatively recent. Other STDs include genital herpes infection, chlamydial infection, trichomoniasis, candidiasis, pediculosis (crabs), scabies, genital or venereal warts, and Gardnerella vaginalis. With the exception of AIDS, most STDs are not fatal, but may result in other complications which may cause or contribute to a person's death. STDs may also have serious consequences for the newborn of infected mothers. Morbidity rates are generally high, causing much disability, pain, and suffering.

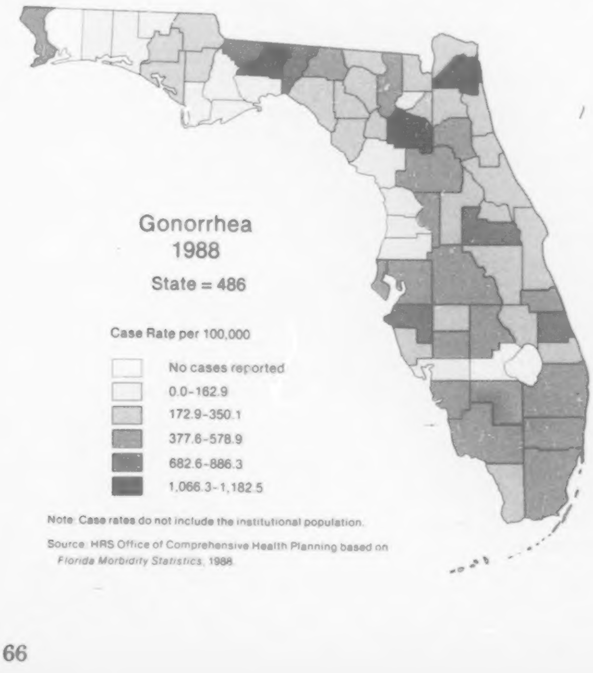
Gonorrhea

Gonorrhea, often referred to as "the clap", is caused by the bacteria *Neisseria gonorrhea* and is transmitted from mucous membranes of infected persons, almost wholly as a result of sexual activity. Even in children it is most frequently a result of sexual contact or molestation. Gonorrhea is of great concern because of its epidemic increase, high reinfection rate, and seriousness of residual effects. The incubation period is usually two to seven days, sometimes longer. The disease produces urethritis in men and women and ophthalmia, severe inflammation of the eyes, in the newborn of infected mothers. Men usually experience pain and discharge, but in females the urethritis is often so mild it goes unnoticed. Women frequently become silent carriers of the disease because they experience no noticeable symptoms.

Pelvic inflammatory disease (PID) is a major complication of gonorrhea in women and a major cause of infertility. PID occurs when bacteria from the cervix spreads to infect the Fallopian tubes through which the egg passes to reach the uterus. Pregnant women can pass this disease to their babies during delivery. Gonococcal ophthalmia of the newborn is first evidenced by redness and swelling of the conjunctiva of one or both eyes and can result in blindness.

Since 1980, the introduction of Penicillinase-producing Neisseria Gonorrhoeae (PPNG), strains totally resistant to penicillin, has impeded control of gonorrhea. The recommended treatment for uncomplicated gonorrhea has changed from penicillin to a relatively new drug called ceftriaxone. Florida has one of the highest rates of PPNG in the nation. A total of 4,909 cases were reported in 1987, a 12.8 percent decrease from 1986. The 1987 morbidity represents the only decrease in PPNG since Florida's efforts to reduce the incidence began over 10 years ago.

Cases of gonorrhea have been reported in Florida since 1918. The peaks in the case rates for gonorrhea parallel the time frames of World War I, World War II and the Vietnam War. The lowest case rates occurred during the 1930's and the 1960's. In 1987, there were 62,944 cases of gonorrhea reported in Florida or 519 cases per 100,000 population. The 1987 figure represents a 6.7 percent decrease over the 67,443 cases reported in 1986. The 1986 number was the largest number of reported cases in Florida in 69 years.



Note: Case rates do not include the institutional population.

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1988.

The number of women with reported gonorrhea in 1987 was 24,957. Of these, 6.3 percent were found to have gonococcal pelvic inflammatory disease (GPID). During 1987, 37,987 men, 60.4 percent of the total cases, were reported with gonorrhea in Florida. The typical infected male was between 20 and 29 years of age, nonwhite, heterosexual and living in the inner-city neighborhoods, where morbidity is highest.

In 1988, 60,714 cases were reported for a case rate of 486 per 100,000 population. This number includes 470 cases which were reported in institutions throughout Florida. The highest gonorrhea case rates in 1988 were found in Leon, Duval, Alachua, Gadsden, St.Lucie, Manatee and Jefferson counties.

Florida's mobile population and high percentage of minorities and foreign-born residents make STD control complex. Another complicating factor in gonorrhea control is that 70-80 percent of infected females are asymptomatic and never seek medical attention.

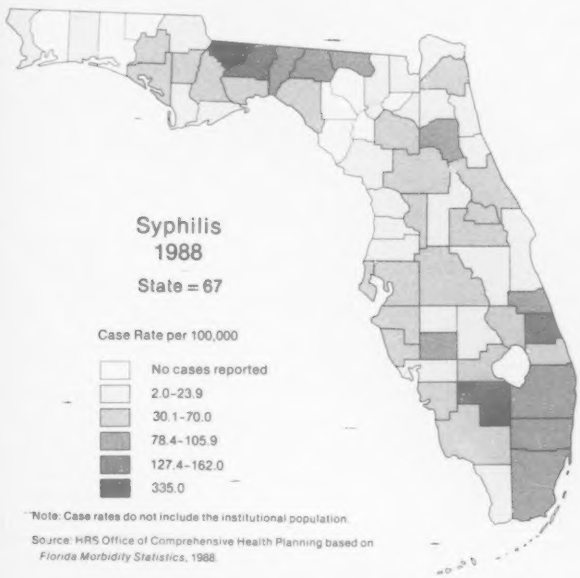
Syphilis

Syphilis is a bacterial disease caused by the spirochete, *Treponema pallidum*, which gains entry into the body through either the mucous membranes or skin during intercourse. Except when transmitted by a pregnant woman to her fetus, the disease is almost exclusively sexually transmitted. The incubation period for syphilis can be 10 days to 10 weeks, but is usually three weeks. If left untreated, the disease progresses through four identifiable stages, primary, secondary, early latent, and late latent. Infectious syphilis (primary or secondary), is characterized by lesions on the mucous membranes, which may disappear spontaneously. The disease may be clinically latent for weeks or years. Late manifestations of the disease may involve the bones, skin, central nervous system, heart and other viscera, and may cause or contribute to the patient's death. Syphilis can be treated successfully, usually with penicillin, at any stage, although the treatment may be lengthier in latent and late syphilis. Also, the damage to the body is much less easily managed in the late stages.

Syphilis cases have been recorded since 1918 in Florida. The highest incidence of syphilis per 100,000 population occurred from 1938 to 1945, a time frame paralleling World War II. In Florida, 15,666 total cases of syphilis were reported in 1987 representing a 66.2 percent increase over the cases reported in 1986 and a 157.3 percent increase since 1980. Florida syphilis levels are the highest in nearly 30 years with an incidence of 129.3 per 100,000 in 1987. Even with a rise in population of 735,482 between 1985 and 1987, the rate per 100,000 for all stages of syphilis jumped from 70.0 to 129.3. Significant increases occurred for all stages of syphilis: primary and secondary, a 71.3 percent increase; early latent, a 68.1 percent increase; and late and late latent, a 54.2 percent increase.

Males accounted for 56.4 percent of the total cases in 1987. Black males comprised the majority of infectious cases, 49.4 percent, and black females represented 32.8 percent of the cases. White males and white females accounted for 7.0 percent and 4.4 percent, respectively, of the infectious cases. The majority of the 7,440 cases of primary and secondary syphilis were reported in persons 15 to 29 years old.

In 1988, 8,378 cases were reported for a case rate of 67 per 100,000 population. This number includes 557 cases reported in Florida institutions. The highest primary and secondary case rates in 1988 were found in Gadsden, Leon, St.Lucie, Hendry, Dade, Desoto and Hamilton counties.



Note: Case rates do not include the institutional population.

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1988.

Congenital syphilis occurs in a newborn who has contracted the disease from the mother. Its trend is even more alarming than primary and secondary syphilis. The current national rate is 12 times higher than at the beginning of this decade, and the Florida rate is about six times the United States rate. In 1987, Florida reported one quarter of all the cases of congenital syphilis in the United States.

Congenital syphilis may result in premature birth or fetal death in pregnancies where the mother is infected. Infants infected *in utero* may have skeletal, neurologic, hematologic, and ocular disorders, nephropathy, and cutaneous lesions. Congenital syphilis, if untreated in the pregnant woman, causes fetal or perinatal death in 40 percent of affected pregnancies.

Congenital syphilis became a reportable disease in Florida in 1957. That year 262 cases were reported. There were 110 reported cases of congenital syphilis in Florida in 1987. Of these, 51 percent were males and 49 percent were females. In 1987, the rate per 100,000 live births was 65.6 in Florida compared to 11.8 in the United States. A review of these reported cases shows that 56.4 percent of the cases were from Dade and Broward counties. Ninety percent of the cases were black and almost three quarters of the mothers received no prenatal care prior to delivery. In 1988, 223 cases were reported.

Acquired Immune Deficiency Syndrome (AIDS)

During May and June of 1981, the Centers for Disease Control (CDC) received reports of several cases with conditions in which the patients' immune systems had been severely compromised without apparent explanation. The term AIDS was first used to describe the new disease in 1982. From those initial cases in 1981, the incidence of AIDS has grown significantly, making it one of the leading public health problems.

AIDS is a life-threatening disease of viral origin which affects the body's natural defense system against disease. It is caused by the retrovirus known as human immunodeficiency virus (HIV). A retrovirus is capable of stimulating a human antibody response which is usually harmless to the virus itself. AIDS is the final stage of a continuum of disease which ranges from persons without symptoms (but capable of infecting others), through less debilitating diseases known as AIDS-related complex (ARC), to full-blown AIDS. ARC is a condition caused by the AIDS virus in which the patient tests positive for AIDS infection and has a specific set of clinical symptoms which are usually less severe than those for AIDS. It is estimated that from two to 10 persons suffer from ARC for every case of AIDS. It is still not known if the progression from HIV infection to ARC to AIDS is inevitable, although many researchers believe that it is. Persons with HIV infection may show no signs or symptoms of illness for seven to 10 years, or longer.

AIDS is a blood-borne disease transmitted by exchange of infected body fluids, especially blood and semen. Behaviors that allow for such exchange of body fluids create a risk for contracting AIDS. This disease is transmitted by intimate sexual contact with an infected person, contaminated needles, exposure to infected blood or blood products, and from infected mothers to the newborn.

In 1985, a test became available to detect the presence of antibodies to HIV. The test is not diagnostic for AIDS, but has proven effective in screening blood products and as a screening mechanism for early detection of HIV infection and early intervention by health care workers.

An estimated 1.5 million Americans are infected with the HIV virus. These infected people are capable of spreading the virus either sexually or by sharing needles, syringes, or other drug paraphernalia. AIDS in adults develops on average, seven to eight years after HIV infection and may appear more than 10 years after seroconversion.

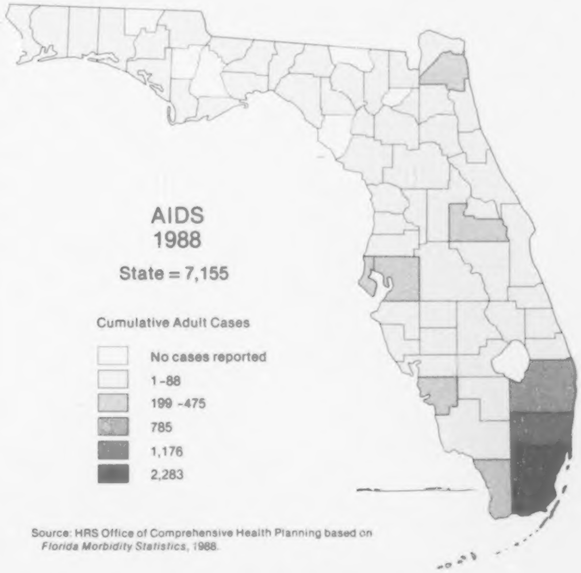
Death for an AIDS patient results from opportunistic diseases, consequences of lowered resistance and loss of immunity. The most common cause of death for AIDS patients is *Pneumocystis carinii pneumonia* (PCP), a rare pneumonia caused by a protozoa parasite. Kaposi's sarcoma, a rare cancer of the tissues beneath the skin and the mucous secreting surfaces of the digestive tract, lymph nodes and lungs, is the second most common cause of death. Tuberculosis is also a common disease among AIDS patients. Numerous other debilitating clinical symptoms are also caused by HIV infection, such as fever, diarrhea, swollen lymph nodes, weight loss, night sweats and exhaustion.

In 1988, there were 9,752 reported cases of AIDS from 50 state health departments in the United States. The number of cases of AIDS among minority groups is disproportionate to their representation in the general population. Eighteen percent of all persons in the United States are black or Hispanic, but these groups comprise over 40 percent of all AIDS cases. Also, 73 percent of female cases and 76 percent of pediatric cases are found among minority groups.

Florida ranks third in the nation, following California and New York, in the cumulative number of reported cases of AIDS. As of April 1, 1989, Florida's cumulative adult cases numbered 7,155. Of the 7,155 cumulative cases of AIDS, deaths occurred in 4,139, or 58 percent of the cases. In 1987 alone, approximately half (49 percent) of the reported cases for that year are reported to have died. There were 1,760 reported cases in 1987 representing a 14.5 case rate per 100,000 population.

In Florida, the age groups between 20 and 39 are the most affected, accounting for 67 percent of the total number of cases. Of the cumulative number of adult cases, 88 percent have been males, 14 percent were attributed to heterosexual transmission and 54 percent to homosexual or bisexual men. Blacks and Hispanics account for approximately 50 percent of the cases. ~~Florida~~ shows a higher proportion of heterosexual contact cases compared to the nation (4 percent). This greater proportion of cases is due primarily to the contribution of non-U.S.- born persons residing in Florida who are presumed to have acquired the disease through heterosexual transmission. One or more cases of AIDS has been reported in 61 counties in the state. Of the 7,155 cumulative adult cases, 16 cases were of unknown county origin and 159 cases were reported by the Department of Corrections. The largest number of cumulative cases of AIDS as of April 1, 1989 were found in Dade, Broward, Palm Beach, Hillsborough and Pinellas counties.

Geographically, Dade County accounted for the majority of adult cases of AIDS diagnosed in 1987 with a total of 479 cases, followed by Broward and Palm Beach counties which reported 293 and 207, respectively. A total of 47 counties throughout the state had at least one case of diagnosed AIDS during 1987, of which the majority, 60 percent, were residents of South Florida at the onset of illness.



Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1988.

As of December 12, 1988, three metropolitan areas of Florida were on the United States Centers for Disease Control's list of the nation's 20 regions with the highest cases of AIDS. Miami ranked eighth with 2,087 cases, Fort Lauderdale ranked 15th with 981 cases, and Tampa Bay (Hillsborough, Pinellas, and Pasco counties) ranked 20th with 714 cases. In compiling the data, the CDC counts only reported cases of full-blown AIDS, including cases in which patients have died. Those who are infected with the disease but who have not developed full-blown AIDS are excluded.

Only New Jersey and New York have reported more cases of AIDS in children than has Florida. As of April 1989, 196 Florida children (under the age of 13) were reported to have contracted AIDS. Of these, 85 percent were infected by parents.

Other Sexually Transmitted Diseases

Several other communicable diseases have been found to be transmitted primarily through sexual contact. Although these diseases are not as critical as AIDS, syphilis or gonorrhea, they still present significant health risks. Several of the diseases can result in harm to an infant if the mother is infected during her pregnancy or at birth. Two diseases, scabies and pediculosis pubis, can be transmitted by arthropods (lice and mites respectively) even if there is no direct sexual contact with an individual infected with one of these diseases. Other diseases may be spread through contact with the feces or other excretions of infected individuals. Certain diseases, such as genital warts, can become malignant.

Candidiasis: Candidiasis is an infection caused by a yeast form. There is a disagreement about whether yeast infections such as candidiasis should be classed as venereal. The overall incidence of candidiasis in the United States is not known. The organism is commonly found on mucous membrane surfaces in women who have no symptoms of infection. This yeast is found in the mouth, gastrointestinal tract, and vagina of 25 to 50 percent of women, making true infection difficult to differentiate. Women having symptoms of this infection most often complain of an inflamed vulva and a vaginal discharge that is thick, white, and curdlike. Little is known about candidiasis occurring in men .

This infection is transmitted by contact with excretions of the mouth, skin, vagina and especially feces from patients or carriers. It can also be transmitted from mother to child during birth. Candidiasis is often present as an opportunistic infection associated with HIV infection.

Chancroid: Chancroid is a sexually transmitted acute bacterial infection clinically characterized by single or multiple painful ulcers at the site of inoculation. Primary lesions appear within one to 14 days after infection. It is found worldwide, but is most prevalent in tropical and semitropical areas where the incidence may be higher than that of syphilis and may approach that of gonorrhea in men. The disease is more common in men.

In American troops in Vietnam, chancroid ranked second in incidence to gonorrhea. In Florida, during 1987, the reported cases of chancroid increased by 127.8 percent, from 345 cases to 786 cases. In 1988, 875 cases were reported which is an 11 percent increase from 1987.

Chlamydial Infection: The chlamydial organisms are increasingly being implicated as causes of human diseases. These organisms are now recognized as important pathogens responsible for a number of sexually transmitted infections, with eye and lung infections the consequences of congenital infections. *Chlamydia trachomatis* is a sexually transmitted genital infection which is manifested in males primarily as a urethritis and in females by mucopurulent cervicitis. Infection is frequently asymptomatic. In women, clinical manifestations are similar to those of gonorrhea. Actually, these infections may be acquired concurrently with gonorrhea and persist after the gonorrhea has been successfully treated with penicillin. Detecting this disease is difficult since 70 percent of females are asymptomatic and since no inexpensive diagnostic test is widely available. It is estimated that 25 to 50 percent of women and 15 to 30 percent of men with gonococcal infections also have chlamydial infections.

Chlamydia trachomatis infection is the most prevalent of all sexually transmitted diseases in the United States, causing approximately 4.7 million infections each year. This is not a notifiable disease in mosts states, however studies have shown that chlamydia now accounts for more endocervical infections and more urethral infections than gonorrhea. An estimated 20 to 30 percent of patients visiting STD clinics have chlamydial infections. Chlamydia is the major cause of nongonococcal urethritis in men and is one of the leading causes of PID and infertility in women.

Chlamydial infections can be transmitted to infants during delivery and cause conjunctivitis and pneumonia. It is also thought that these infections contribute to low birth weight and prematurity.

Genital Warts: Genital warts, caused by a virus, are the fourth most common sexually transmitted disease in men and the third most common in women. There are approximately 500,000 cases per year in the United States. Genital warts enlarge during pregnancy and may cause hemorrhage or obstruction during delivery. They can also become malignant.

Granuloma Inguinale (Donovanosis): Donovanosis, commonly called granuloma inguinale, is believed to be most often transmitted by sexual contact. The infection is caused by Donovania, or Donovan bacillus. The disease is mildly contagious and probably requires repeated exposures for spread of infection It is apparently more frequent among males than females and among persons of lower socioeconomic status. Granuloma inguinale predominantly occurs between the ages of 20-40 and in the United States is most common among homosexual men.

Granuloma Inguinale became a reportable disease in Florida in 1945, after World War II, and continued to be reportable until 1979. The largest number of cases were reported from 1945 to 1952.

Hepatitis B: Hepatitis B is one of several hepatitis viruses. The disease may result in abdominal pain, nausea, vomiting, and jaundice and frequently causes liver damage including cirrhosis and liver cancer. Long-term problems frequently occur when the disease is transmitted in utero from mothers to newborns. The virus usually is transmitted through exposure to infected blood or blood products although it may also be spread through sexual contact. High risk groups include drug abusers, homosexuals, patients requiring frequent blood transfusions or hemodialysis and health care workers.

Vaccines are available, but are expensive and usually are not administered except to health care workers who routinely handle blood and blood products and occasionally to members of other high risk groups. Current Florida laws do not require hepatitis B immunizations for any group.

Hepatitis A and B were reported together from 1950 to 1965 in Florida. Since 1966, hepatitis B has been reported separately and has shown a substantial increase in the case rate. Florida reported 1,563 cases of hepatitis B in 1987, a case rate of 12.9 per 100,000. In 1988, 1,480 cases were reported for a case rate of 14.7 per 100,000.

Herpes Genitalis: Herpes genitalis is caused by herpes simplex virus (HSV) type 2. It occurs principally in adults. Lesions appear in the genital and perineal areas as well as the mouth, depending on sexual practices. The symptoms go away, but the virus persists in a latent or unrecognized form in most patients. Various precipitating factors may cause the latent infection to become clinically apparent as recurrent herpes. Herpes spreads to sexual partners usually during active manifestation of the disease. Its chronicity, frequent recurrences, and difficult treatment and prevention distinguish it from other STDs.

It is estimated that 724,000 new cases of genital herpes are reported annually in the United States, resulting in a cumulative prevalence of over 20 million infected persons. Its peak incidence parallels the young age groups affected by other STDs. Herpes genitalis is a lifelong disease once acquired. Even though most people with the disease suffer recurrences, in many cases, each successive episode is more brief and mild. However, it can carry with it not only intense and recurrent discomfort, but also anxieties about future childbearing, malignancy, and sexual and marital function.

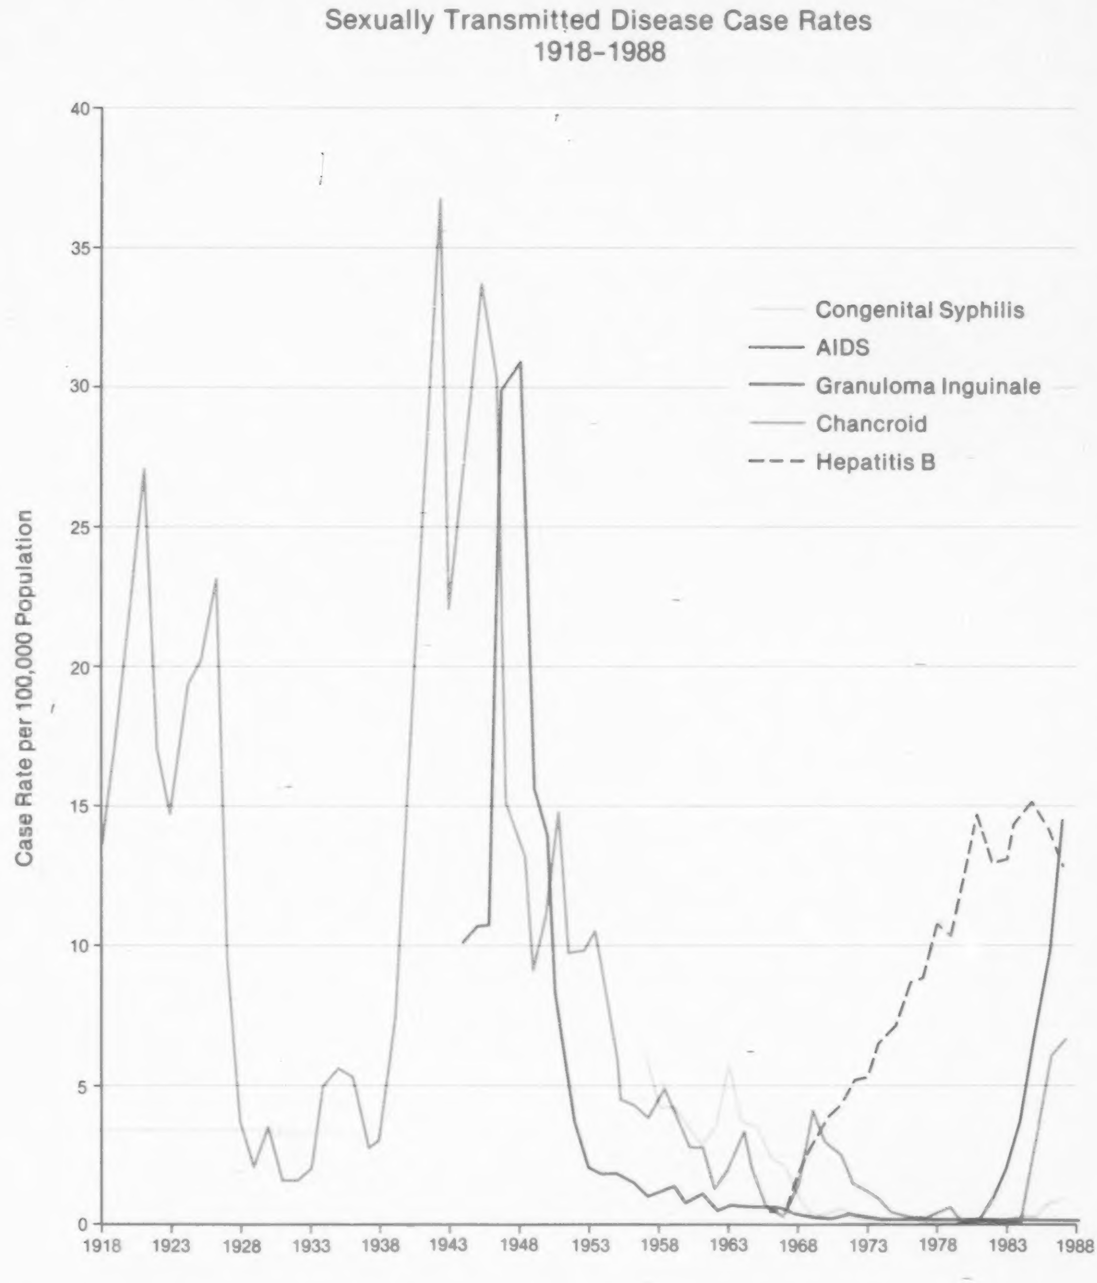
In early pregnancy, women infected with herpes have an increased chance of miscarriage. Vaginal deliveries of pregnant women with active genital infections carries a high risk of infecting the fetus or the newborn, causing blindness, neurological problems, mental retardation, and even death. It is estimated that 3 to 5 percent of infants born through an infected birth canal will acquire a neonatal herpes infection. The incidence of this occurring is estimated to be between one in 3,000 and one in 20,000 live births. Genital infection with HSV type 2 also increases the risk of later cervical cancer in women.

Lymphogranuloma Venereum: Lymphogranuloma venereum (LGV) is a systemic, sexually transmitted disease caused by Chlamydia organisms which spreads by way of the lymphatic system. Reports of the incidence of LGV indicate fewer than 1,000 cases annually in the United States. The symptoms of LGV resemble those of other STDs, and its reported incidence may be influenced by this.

Pediculosis Pubis: Pediculosis pubis, also known as "crabs," is caused by pubic lice. Although lice can be transmitted by bedding or clothing they are often transmitted during sexual contact.

Scabies: Scabies, a highly communicable skin disease, caused by itch mites known as *Scarcoptes scabiei*, is transmitted by close body contact, bedding and clothing.

Trichomoniasis: A one-celled parasite called trichomonas, is the causative organism of *Trichomonas vaginalis.* The parasite is found in both men and women and is most often communicated through intercourse. However, it can also be passed on by moist objects such as towels, bathing suits, underwear, washcloths, toilet seats and benches in locker rooms. During the postpartum period in women who have trichomoniasis, prolonged vaginal discharge and endometritis is twice as high as in women who do not have the organism. In men, urethritis and its symptoms of discharge, itching, burning and inflammation are the signs of this disease most often seen.



Sexually Transmitted Disease Case Rates
1918-1988

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1918-1988.

Food-Borne Diseases

Food poisoning is a generic term that refers to illnesses acquired through consumption of contaminated food or drink. The five most common factors contributing to food-borne disease, in order of frequency of occurrence, are improper holding temperature, food from an unsafe source, inadequate cooking, poor personal hygiene, and contaminated equipment.

Food poisoning outbreaks are usually recognized by the sudden occurrence of illness within a short period of time among individuals who have consumed one or more foods in common. Single cases of food poisoning are difficult to identify unless there is a distinctive clinical syndrome, as in botulism. Almost all reported cases of food poisoning are caused by bacteria or by poisons produced by bacteria. This poison cannot be detected by taste, odor, or color and forms in food before it is eaten. There are four main types of food poisoning:

- Infections, caused by germs that are allowed to grow in food, e.g. salmonellosis;
- Intoxications, caused by poisons produced by germs which are not destroyed by cooking temperatures, e.g. staphylococcus and botulism;
- Intestinal disorders, caused by eating foods that have been improperly cooked or refrigerated, thus allowing contaminants to grow to a level infectious to man, e.g. *Vibrio parahaemolyticus* and *Clostridium perfringens*; and
- Chemical food poisoning which is caused by contamination of food by chemicals such as pesticides used in insect and rodent control, certain cleaning compounds, and sometimes by use of improper containers for cooking or storing.

Botulism

Botulism is a serious intoxication characterized by weakness, extreme dryness of the mouth, and oculomotor or other symmetrical motor cranial-nerve paralyses. Clinical symptoms relate primarily to the nervous system. Loss of eyelid control, visual difficulty (blurred or double vision), and sore throat are often the first complaints. Vomiting and diarrhea may be present initially. About one-third of patients die within three to seven days, usually from respiratory failure or from superimposed infection.

This germ is found in soil, water, and the intestinal tract of animals, including fish. It can grow without exposure to air. The toxin is produced in improperly processed foods, usually those that have been either canned or preserved at temperatures not high enough to kill the botulinum spores. Sources of danger are low-acid foods such as string beans, corn, beets, and seafood.

Botulism is transmitted by eating contaminated foods, predominantly from jars or cans inadequately processed during canning and eaten without subsequent adequate cooking. Most poisonings in the U.S. are due to home-canned vegetables and fruits or to fish; poisoning from meats are infrequent.

Botulism has been a reportable disease in Florida since 1960, however the first case was not reported until 1975. Since then, a total of eight cases have been reported. In 1987, three cases of botulism, the largest number reported in a single year were reported in Sarasota County. One case was reported in 1988 in Highlands County.

Clostridium Perfringens

Sudden onset of abdominal colic followed by diarrhea characterizes this intestinal disorder. Nausea is also common but vomiting is usually absent. This is generally a mild disease of short duration, usually one day or less and is rarely fatal in healthy persons. Type A strains of *Clostridium perfringens* cause typical food poisoning. These organisms grow in the soil and gastrointestinal tract of man and animals such as cattle, pigs, poultry and vermin.

Clostridium perfringens is transmitted by eating food contaminated by feces or soil in which conditions have permitted the organism to multiply. Almost all outbreaks are associated with inadequately heated or reheated meats, usually stews, meat pies, or gravies made of beef, turkey or chicken. Outbreaks are usually traced to facilities that have inadequate cooking and refrigeration for large scale service. These have included food catering firms, restaurants, cafeterias and schools. Since this disease is not reportable, its incidence rate in Florida is unknown.

Salmonellosis

Salmonellosis is a communicable bacterial disease with clinical symptoms of acute gastroenteritis, sudden onset of abdominal pain, diarrhea, nausea, vomiting and fever. Salmonella can be particularly dangerous when contracted by infants or small children. Dehydration, especially among infants, may be severe. There is no specific treatment, and antibiotics may be contra-indicated. The main mode of transmission is eating of contaminated food, but salmonella pathogens have also been found to be present in Florida's estuarine environments and can be ingested directly from the water. Transmission to humans can also be by the fecal-oral route.

Bacteria of the genus *Salmonella* are found in the intestines of birds and animals and on the feet and bodies of roaches and flies. Animals including dogs, cats, and frogs can harbor the disease. It can also be carried by a healthy person. Foods most susceptible to growing *Salmonella* are poultry, meats, dairy products and eggs, smoked fish, and prepared dishes such as custards, chicken salad, egg salad, and ham salad. This disease usually serves as an indicator of inadequate sanitary practices in food preparation.

Cases of salmonellosis have been reported in Florida since 1950. There have been significant increases in the case rate trend since that time. However, these increases may be the result of more accurate diagnostic and reporting procedures over the years. In 1950, the case rate per 100,000 population was 1.4 with 39 cases reported. The overall rate of Salmonella has increased since 1976, with brief decreases in the years 1980 and 1984. There were 2,960 reported cases in Florida in 1987, a case rate of 24.4 per 100,000, which represents a slight decrease from 1986. In 1988, 2,435 cases were reported for a case rate of 19.5 per 100,000 population.

Staphylococcus

Staphylococcus is an intoxication (not an infection) of abrupt and sometimes violent onset, with severe nausea, cramps, vomiting, usually diarrhea, and prostration: sometimes with subnormal temperature and markedly lowered blood pressure. Deaths are rare. Duration is usually not more than a day or two. It can be easily spread by a food service worker with a cold or sinus infection, a cut or burn, boils or infected pimples (Staphylococcus germs cause the common boil and may be the cause of infected pimples).

Staphylococcus is one of the principal causes of acute food poisoning in the United States. It is both widespread and occurs relatively frequently. The staphylococcus germ is carried by man and occasionally cows. Foods most often contaminated from human origin are pastries, custards, salads and salad dressings, sandwiches, sliced meats, and meat products. Contaminated milk and milk products have also been implicated in extensive outbreaks. This germ multiplies in foods allowed to stand in room temperatures for several hours before serving.

Vibrio Parahaemolyticus

This intestinal disorder is characterized by watery diarrhea and abdominal cramps with nausea, vomiting, fever, and headaches also occurring in the majority of cases. The disease generally lasts 1-7 days and is of moderate severity. Death rarely occurs. Vibrios are found in coastal waters during warm seasons and are a natural contaminant of fish and shellfish. Organisms are found in marine silt during cold seasons.

Vibrio parahaemolyticus is transmitted by eating raw seafood that has been inadequately refrigerated or cooked to destroy naturally contaminating vibrios or by eating food that has been contaminated due to handling in the same environment as raw seafood. Person-to-person spread does not appear to occur.

In 1986, there were 57 reported cases of vibrio infections in the state. Sixty-seven percent of the cases were associated with seafood consumption, primarily raw oysters. The counties reporting the most infections were Leon and Hillsborough. The largest number of cases were reported in April, followed by May and March.

In 1987, there were 81 reported cases of vibrio infections in the state. Seventy percent of the patients were male and the median age of the patient was 40. Fifty-five percent of the cases were associated with raw oyster consumption. Leon, Bay, Duval and Hillsborough were the counties reporting the most infections. The month with the peak number of cases was May, followed by July, and September. Fourteen cases were reported in 1988, with Hillsborough and Broward County reporting the most infections, three and four cases, respectively.

Water-Borne Diseases

Water-borne illnesses may be contracted by bathing or swimming in areas contaminated by sewage, consuming seafood that has been harvested from contaminated waters or by drinking contaminated water. The following diseases can be transmitted by contaminated water.

Amebiasis

This infection is caused by a parasite. Although most infections are asymptomatic, fever, chills and bloody diarrhea can occur. The disease can be transported through the blood stream, producing liver abscess or less commonly, lung or brain abscess. In epidemics, amebiasis is transmitted primarily by water contaminated with infected persons' feces. Endemic spread is by hand-to-mouth transfer of fresh feces, by contaminated raw vegetables, flies, soiled hands of food handlers, or water. Some people have been infected by swimming in lakes that contain the parasite. There were 62 reported cases of amebiasis in 1987, but none in 1988.

Campylobacteriosis

Campylobacter is a bacterium which is very similar to salmonella. Campylobacteriosis is characterized by bloody diarrhea and fever. The onset of the disease is usually abrupt. Poultry is a predominant source of *Campylobacter*, while contact with pets and consumption of raw milk or surface water also play important roles. Florida reported 1,662 cases of campylobacteriosis in 1987, a case rate of 13.7 per 100,000. The 1988 case rate was 15.5 per 100,000.

Cryptosporidium

This is a parasite which is similar to *Giardia*. In contrast to bacterial infections, the onset of illness is slow and lasts longer. Symptoms include diarrhea and bloating. Contaminated water is a major source of this parasitic disease.

Giardiasis

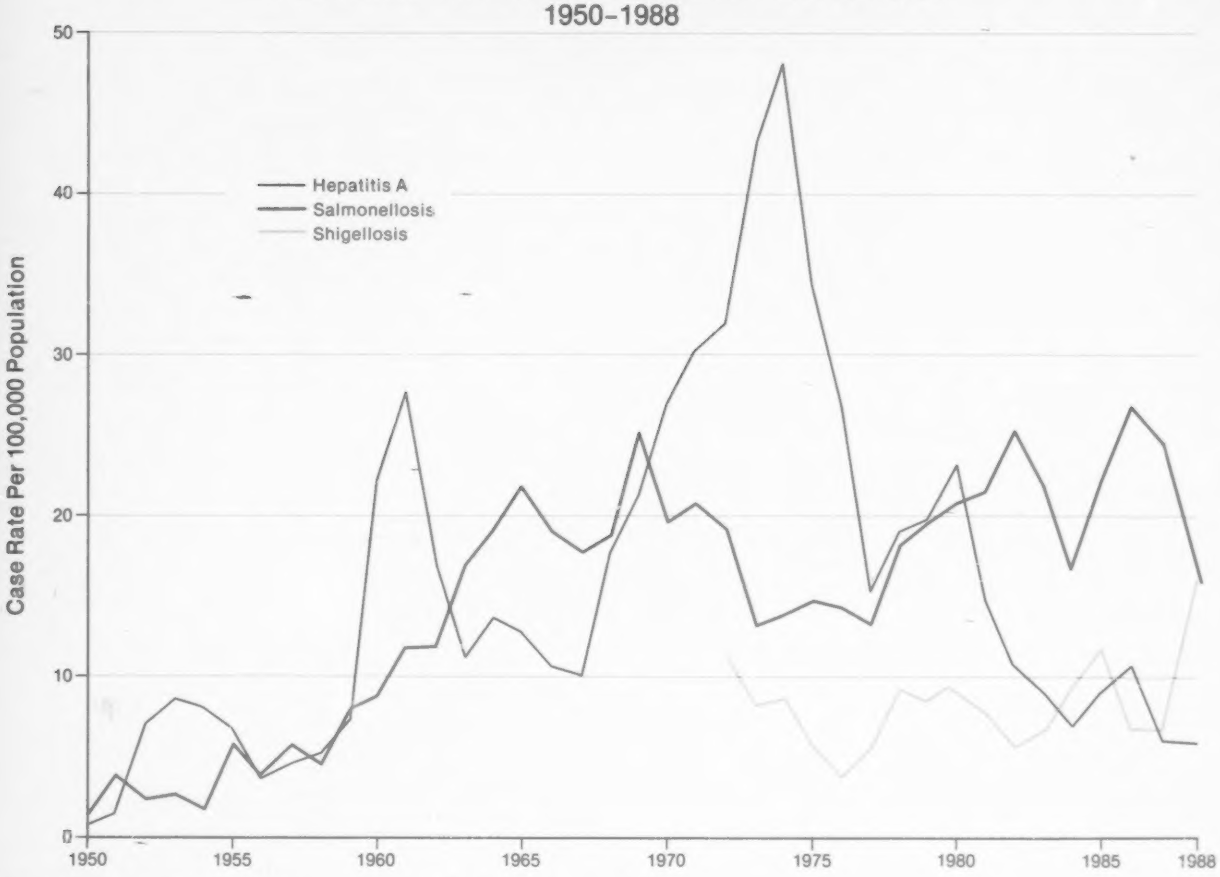
Giardiasis is a protozoal infection of the small bowel. It is associated with a variety of intestinal symptoms, such as severe diarrhea, abdominal cramps, bloating, fatigue and weight loss and may lead to debilitating disease due to dehydration. Children are infected more frequently than adults. Most infections are attributed to fecal contamination of water and exposure to an infected, diaper-age child in a day care setting. The *giardia* organism is the most common enteric pathogen identified in children who attend day care centers.

Transmission to humans directly from animals via the fecal-oral route is also possible. Direct transmission to humans from animals usually occurs among hunters dressing a kill or from handling of live wildlife. Florida reported 1,747 cases in 1988.

Hepatitis A

The onset of this virus is usually abrupt with fever, malaise, anorexia, nausea and abdominal discomfort, followed by jaundice. The infectious agent is found in feces. Contaminated water and food, including milk, sliced meats, salads, and raw or undercooked mollusks are common methods of transmission.

Hepatitis A has been a reportable disease in Florida since 1950, but from 1950 to 1966 hepatitis A and B were reported together. In 1974, 4,079 cases (48 per 100,000) were reported; the largest number to date. More recently, the Florida case rate for Hepatitis A has declined from 10.8 per 100,000 in 1986 to 6.0 in 1987 and to 5.9 in 1988.



Food-Borne and Water-Borne Disease Case Rates
1950–1988

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1950–1988.

Paratyphoid Fever

Paratyphoid fever is a generalized bacterial enteric infection, which causes fever, enlargement of the spleen, diarrhea and sometimes rose spots on the trunk of the body. The bacterium is transmitted through direct or indirect contact with feces or urine of infected individuals. It is spread by food, especially milk, milk products and shellfish. A few outbreaks are related to water supplies, including swimming waters.

Shigellosis

Shigellosis is an acute bacterial disease which primarily involves the large intestine. The disease causes diarrhea, accompanied by fever and often vomiting and cramps. Two-thirds of the cases, and most of the deaths from this disease, are in children under 10 years of age. Transmission is by direct or indirect fecal-oral transmission from a patient or a carrier. Water, milk and fly-borne outbreaks may occur as the result of direct contamination with feces.

Shigellosis became a reportable disease in Florida in 1972. That first year, 863 cases (11.2 per 100,000) were reported. Florida reported 818 shigellosis cases in 1987, a case rate of 6.8 per 100,000, the same as in 1986. However, the case rate for 1988 increased to 16.0 per 100,000 with 1,995 cases reported, the largest number of occurrences ever reported.

Air-Borne Diseases

Air borne diseases are those diseases which are transmitted from a reservoir by way of the dissemination of microbial aerosols to a susceptible human, usually entering the body through the respiratory tract. Microbial aerosols are suspensions in the air of particles consisting partially or wholly of microorganisms. They may remain in the air suspended for long periods of time, some retaining and others losing infectivity or virulence.

Tuberculosis

Tuberculosis is a chronic mycobacterial disease which, although under control in most developed countries, is a major cause of death in the Third World. Tuberculosis is primarily a pulmonary disease; however, almost any organ in the body can be affected. Transmission is usually via airborne droplets from the mouths of infected persons.

Tuberculosis cases have been recorded in Florida since 1918. In 1900 tuberculosis was the second ranking cause of death in the United States. In the 1920's, when it killed more people than cancer, there was no pharmaceutical cure. Prior to the 1960's, treatment for tuberculosis was patient isolation in sanatoriums to prevent person to person infection. Treatment of the disease changed markedly during the 1960's. Antibiotics became available for outpatient therapy so that patients could be discharged sooner from the hospital and preventive therapy was given to positive tuberculin reactors to prevent the development of active tuberculosis. The death rate in Florida fell from 19 per 100,000 in 1950 to less than 2 per 100,000 in 1969. The death rate in 1986 was 1.2 per 100,000.

During the 1960's the number of reported new cases increased primarily due to an influx of Cuban refugees, migrant farm workers and new cases from other states. More new drugs were added in the early 70's. Since 1971, the number of new cases reported and the case rates have remained relatively constant in Florida. In 1971, the case rate per 100,000 was 20.8 with 1,515 cases reported. In 1987, 1,586 cases of tuberculosis were reported in Florida, representing a case rate of 13.2 per 100,000. However, this rate is approximately one and a half times the U.S. figure. Compared to 1986, this is a 7.3 percent increase in the number of cases and a 4.8 percent increase in the case rate. During 1988, 1,668 new cases were reported representing a case rate of 13.3 per 100,000. This situation is partly attributable to the current AIDS epidemic since tuberculosis is an opportunistic disease affecting many AIDS patients.

The probability that human immunodeficiency virus (HIV) is a major cause of the failure of tuberculosis rates to decline in Florida is suggested by the prevalence of tuberculosis among AIDS patients. Of all AIDS cases diagnosed in Florida since that epidemic began, nearly 8 percent have been found to have active tuberculosis. The immunosuppressive effects of an HIV infection can activate tuberculosis in individuals infected years earlier, often before the appearance of AIDS.

Florida has many of the predisposing conditions for tuberculosis, including an older population and a high proportion of immigrants and residents from Third World countries, such as Haiti, where infection is widespread. In 1986, for the sixth straight year, Miami had the highest case rate (46 per 100,000) among the nation's cities of over 250,000 population. Miami's high rate continued in 1987 and 1988, as the impact of AIDS added a new dimension to the control of tuberculosis. Dade County had 401 reported cases of TB in 1987 and 430 in 1988, accounting for 25.3 percent and 25.8, respectively, of the state's total number of cases for those years. Among the 50 states, Florida ranked fourth in the number of reported tuberculosis cases in 1986, and eleventh in case rate per 100,000 population.

The failure of case rates to decline is most evident in major urban centers of the state, but tuberculosis in Florida, unlike other parts of the nation, cannot be described as a predominantly urban problem. In Florida, the rate for tuberculosis in 45 of the state's most rural counties in 1986 was 11.5 per 100,000, compared to 12.8 in the remaining 22 counties, a difference of only 11 percent. In the state as a whole, tuberculosis among the native-born black male population remains an intractable problem. In 1987, the rate per 100,000 population for white females was 3.6; for white males, 10.7; for nonwhite females, 28.9; and for nonwhite males, 69.4 per 100,000. Rates for all race and sex categories were the highest in the 45-64 age group, with nonwhite males in this group experiencing a case rate of 160.7 per 100,000.

Children under age 15 accounted for 45 cases of tuberculosis in 1987, a decrease from the previous year. This statistic shows that a part of Florida's current tuberculosis morbidity increase can be attributed to recent transmission and not to activation of latent infection.

Of the 1,586 tuberculosis cases reported in Florida during 1987, 142 or 9.0 percent died from TB that year. Also of the approximately 1,400 TB patients under medical supervision during 1987, 10.7 percent died within a year. The 1986 unadjusted death rates per 100,000 were white males 1.2, white females 0.5, nonwhite males 5.0 and nonwhite females 1.7. While AIDS, lung cancer, chronic obstructive lung disease, and other grave illnesses were contributing factors in many deaths, some preventable deaths occurred primarily due to advanced tuberculosis.

Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1918-1988.

Influenza and Pneumonia

Influenza and pneumonia are two of the major infectious diseases of the respiratory system. Although the death rates from both pneumococcal pneumonia and influenza have fallen in recent years, these diseases still kill a large number of elderly Floridians annually. All forms of influenza and pneumonia, when combined, rank as the sixth-leading cause of death in Florida. Approximately 80 percent of these deaths occur among those 65 and older. In 1986, 2,896 deaths were attributed to pneumonia and influenza for an age adjusted death rate of 9.7 per 100,000. The unadjusted death rate is 24.7 per 100,000. The counties having the highest unadjusted rates per 100,000 were Lafayette with 64.2, Franklin with 58.6 and Hamilton with 53.9.

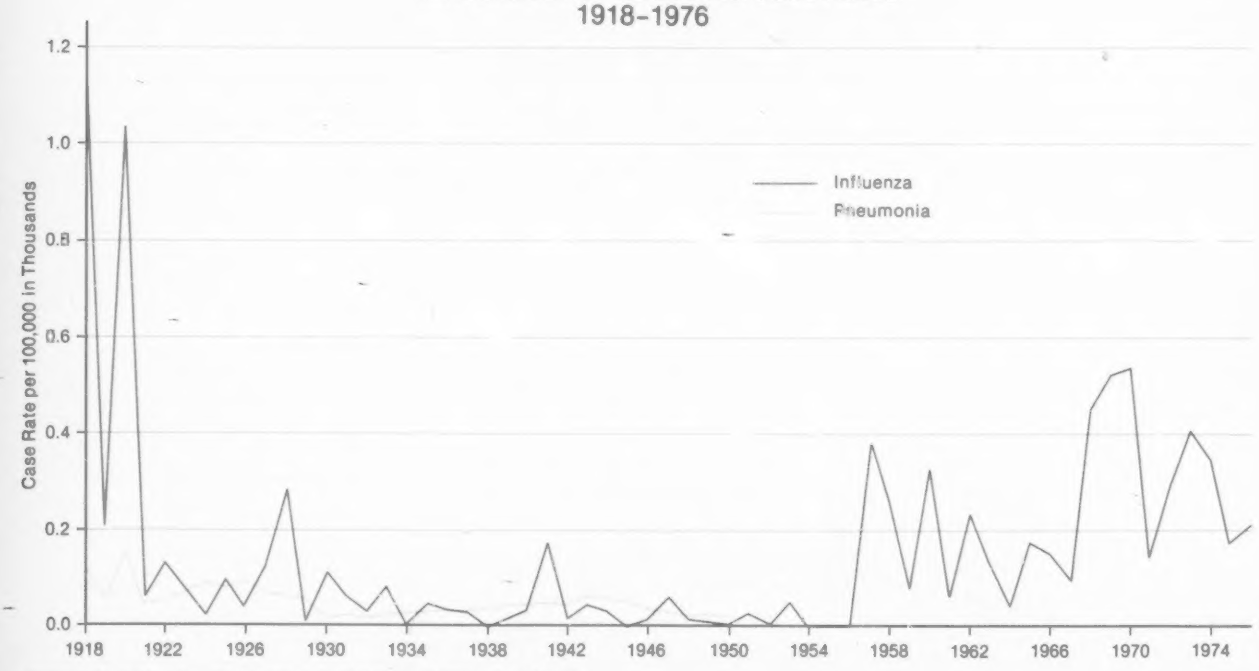
Influenza: Influenza is an acute infectious disease of the respiratory tract characterized by abrupt onset of fever, chills, headache, sore throat, and cough. Man is the reservoir of human infections, although pigs, horses, and birds are suspected as sources of new human strains. Transmission is by direct contact, through droplet infection, or by articles freshly soiled with discharges of the nose and throat of infected persons; probably airborne among crowded populations in enclosed spaces such as barracks, ships or school buses. The incubation period usually lasts 24 to 72 hours. The period of contagiousness is usually three days from the onset of symptoms. Recovery often occurs in two to seven days.

Influenza is serious because of the rapidity with which epidemics evolve, the height of the attack rates, and the seriousness of complications, notably bacterial pneumonia and bacterial meningitis. In general, incidence is highest in school-age children with rates decreasing progressively among adults as age increases, with the exception of the elderly. Severe disease and death normally occur among the very young, the elderly, and those debilitated by chronic disease.

While epidemic fatalities generally are low, epidemics are associated with a general mortality much in excess of non-epidemic expectancy. Approximately 62,000 additional deaths occurred in the U. S. during the pandemic of influenza type A in 1957-58 than would normally be expected, and 27,900 additional deaths were estimated to have occurred during the 1968-69 epidemic due to the Hong Kong strain of type A. Attack rates during epidemics range from less than 15 percent to 25 percent in large communities, to 40 percent or higher in closed populations. Major epidemics tend to be periodic: epidemics of influenza type A have appeared in the U. S. at intervals of two to three years; influenza type B usually not less than four to six years. Influenza has not been a reportable disease in Florida since 1976, therefore specific Florida data on recent occurrence is not available.

Pneumonia: Acute pneumonias are responsible for 10 percent of hospital admissions in the United States. They are most common during the winter and early spring. Persons of any age are susceptible, but pneumonia is more common among infants and the elderly. It is found both in persons without underlying disease and in those with diminished defense mechanisms. Commonly there is a history of alcoholism, recent respiratory tract infection, or viral influenza. Onset is usually sudden with a shaking chill, fever, chest pain, and a cough. Antibiotics are quite successful in arresting the disease and a vaccine for pneumococcal pneumonia is 80-to 90-percent effective in adults. The vaccine is generally given to people who might die from pneumonia. Pneumonia has not been a reportable disease in Florida since 1950.

Influenza and Pneumonia Case Rates
1918–1976



Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1918–1976.

Zoonotic Diseases

Zoonotic diseases or zoonoses are communicable diseases transmitted from animals to man. Due to its subtropical climate and large areas of natural vegetation and swampland, Florida is a reservoir for many zoonoses which are uncommon in other states. Florida's role as a major entry port for goods from the Caribbean and South America also results in the entry of diseases from foreign countries.

Most of the zoonotic diseases have been controlled as a result of improved public health practices - rodent control, arthropod control, improved hygiene and sanitation practices, and inspection of foreign imports. Although the number of cases of these diseases in Florida is small, the potential for infection remains high. Rabies is a zoonoses which is not treatable, although post-exposure immunizations may be given to prevent the disease. Zoonoses that may result in death without prompt treatment include bubonic plague, encephalitis, leptospirosis, and Rocky Mountain spotted fever. Other zoonotic diseases include ehrlichiosis, histoplasmosis, Lyme disease, typhus fever, psittacosis, and toxoplasmosis.

Arthropod-Borne Encephalitis

Several types of arthropod-borne viral encephalitis are transmitted to humans from animal reservoirs including birds, bats and reptiles, through the bites of infected mosquitoes. In Florida, the most common types are St. Louis encephalitis (SLE) and eastern equine encephalitis (EEE). The diseases result in inflammation of the brain, spinal cord and meninges causing symptoms that may include headache, fever, convulsions, coma and death.

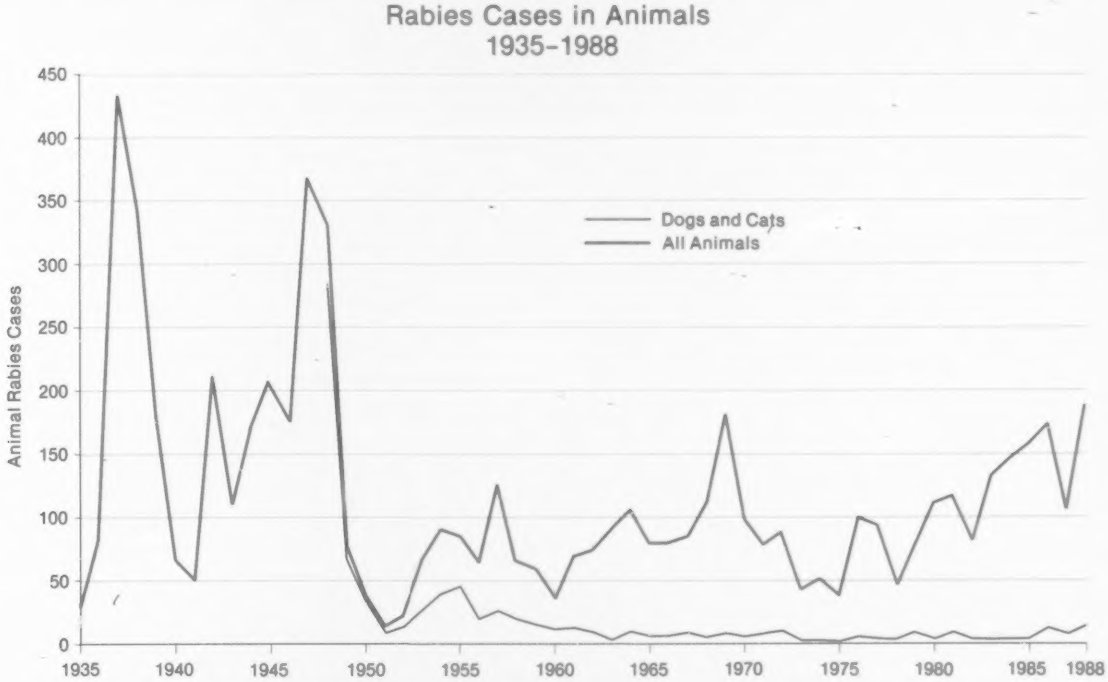
All types of encephalitis have been reported in Florida since 1927. However, SLE was first isolated in Florida in 1952. Epidemics have occurred in 1959, 1961, 1962, and 1977. In 1977, an outbreak of SLE resulted in 78 cases or a case rate of 0.9 per 100,000. In both 1987 and 1988 one case of EEE was reported.

Rabies

Rabies is an acute infectious viral disease usually transmitted by contact with an infected animal. If untreated, it is invariably fatal. Symptoms in humans usually occur after an incubation period of 20-60 days and include headache, fever, irrational behavior, violent spasms and extreme thirst. The principal animal reservoir in Florida is the raccoon, followed by bats, foxes, cats, dogs, skunks, and bobcats. All mammals have the potential to be infected.

Dog and cat rabies have been reported in Florida since 1934 and total animal rabies have been reported since 1947. The number of reported cases of dog and cat rabies declined significantly from 1947 to 1960 and remained fairly constant from 1960 to 1985. Total animal rabies has also declined since 1947. Over the past 10 years, reported rabies cases in wildlife have climbed. Although the number of cases in domestic pets (dogs and cats) have represented a small share (4.7 percent) of all animal rabies, there has been a tripling in the two-year average of these pet rabies cases since 1985. At least three counties (Duval, Leon and Orange) have instituted rabies quarantines within the past two years. The potential danger of rabies exposure is increasing annually as civilization encroaches on previous wildlife habitats.

No human cases of rabies have been documented since 1948 in Florida, but the number of cases of human exposure to rabies from animal bites has been increasing. The number of cases of animal bites of humans has also been increasing to approximately 35,000 cases per year.



Source: HRS Office of Comprehensive Health Planning based on *Florida Morbidity Statistics*, 1935-1988.

Tick-Borne Diseases

Ehrlichiosis: *Ehrlichiosis* is a recently discovered zoonotic disease caused by a rickettsial agent which is transmitted to humans by the bite of infected ticks. The disease causes symptoms similar to those for Rocky Mountain Spotted Fever, but a rash occurs much less frequently. Fever and hematologic abnormalities are present in over half of all cases. Since ehrlichiois is not a reportable disease in Florida, accurate data on cases is not available.

Lyme Disease: Lyme disease is transmitted to humans by the attachment of ticks, specifically those infected by a spirochete, *Borrelia burgdorferi*. Animal reservoirs are primarily the white-footed mouse and white-tailed deer. The disease results in flu-like symptoms and a skin lesion around the bite within 30 days. This may progress to complications involving the heart and/or nervous system, as well as joint pain, weeks to months after initial exposure or the first symptoms appear. The third stage is arthritis which may result months to years after initial symptoms. Florida does not report Lyme disease and data on cases is limited.

Rocky Mountain Spotted Fever: Rocky Mountain spotted fever is transmitted to humans by ticks found on both domestic and wild animals. The disease causes fever, headaches and a rash and can damage the liver, lungs and kidneys, possibly causing death. Most Florida cases are contracted from forested areas in the Panhandle and north central Florida. Rocky Mountain spotted fever has been a reportable disease in Florida since 1941 with a case rate consistently less than one per 100,000 population. During the past ten years, a total of 76 cases were reported. The greatest number of cases (15 cases) were reported during 1985 resulting in a 0.1 case rate per 100,000 population. A total of five cases were reported in 1988 for a case rate of 0.04 per 100,000.

Other Related Animal-Transmitted Diseases

Brucellosis: Brucellosis is a systemic disease transmitted to humans through contact with the blood, tissues, urine or other discharges of infected animals, especially swine and cattle. Florida cases frequently occur in hunters who have handled or eaten meat from wild hogs. The disease may also be contracted through ingestion of milk or dairy products from infected animals. Symptoms include headache, chills, weakness, depression and generalized aching occasionally with pneumonitis.

The first cases of brucellosis were recorded in Florida in 1943. The number of cases declined from 1962 to 1974 with an average of four cases reported each year. From 1975 to 1987 the average number of cases reported each year increased to 10 with the largest number (16 cases) reported in 1981 for a case rate per 100,000 population of 0.16. In 1988, five cases were reported resulting in a case rate of 0.05 per 100,000 population.

Psittacosis: Psittacosis is a chlamydial disease transmitted to humans usually through inhalation of dust contaminated with the feces of infected birds. The disease, which most frequently affects bird handlers or owners of pet tropical birds, infects the lungs and causes symptoms ranging from flu to pneumonia.

No cases of psittacosis were reported from 1950 to 1957, although it was a reportable disease during this time. An average of 4.3 cases per year were reported from 1957 to 1987. The largest number of cases ever reported during a single year (14 cases) occurred during 1985 for a case rate of 0.1 per 100,000 population. There were two cases reported in 1987 and one in 1988.

Histoplasmosis: Histoplasmosis is a fungal disease contracted through inhalation of dust containing the fungus, generally from bird roosting areas such as chicken houses, pigeon roosts and bat caves. All Florida cases since 1955 were attributed to exposure to bat enclosures. The symptoms may include fever, respiratory distress, diarrhea, weakness, and anemia leading to death in severe cases. Histoplasmosis has been a reportable disease in Florida since 1954. The largest number of cases reported in a single year (25 cases) occurred during 1973. There were four cases reported during 1987 and one case during 1988.

Leptospirosis: Leptospirosis is a spirochete bacteria which is generally contracted through contact with dogs or farm animals such as horses, pigs and cattle. Generally, the disease organism enters the bloodstream through a cut, causing symptoms such as fever, vomiting, headaches and sometimes meningitis or kidney failure. On average, 5.7 cases have been reported each year since 1950 when the disease became reportable. The highest incidence of the disease occurred during 1968 - 1970 (42 cases) and 1978 - 1980 (51 cases), accounting for 44 percent of all reported Florida cases. There were no cases reported during 1987 and one case reported during 1988 in Lee County.

Toxoplasmosis: Toxoplasmosis is a protozoal disease that may be transmitted directly to humans from animals through contact with animal feces, particularly from birds and cats. Symptoms are often mild but may include a sore throat, fatigue and enlarged lymph nodes. In pregnant women, the disease may be transferred to the fetus causing blindness and other birth defects. Toxoplasmosis became a reportable disease in Florida in 1964. Ninety cases were reported between 1979 and 1982, representing 67 percent of all Florida cases. Since 1982, 29 cases have been reported including four cases in 1987 and eight in 1988.

Typhus Fever: Typhus fever is transmitted to humans by bites of infective rat fleas. Although rats are the most common reservoir for this disease, opossums, cats and possibly other wild or domestic animals may serve to transport infective fleas when in proximity to humans. The disease causes headache, chills, prostration, fever, pains, and skin eruptions. The fatality rate for all ages is about 2 percent but increases with age. One attack confers immunity.

Formerly, thousands of cases occurred yearly in the United States with cases concentrated in the southeastern states. One hundred to four hundred cases a year were reported in Florida from 1939 to 1948. However, due to improved rodent control measures and the use of residual insecticides the number of cases has been drastically reduced. Currently fewer then 50 cases are reported annually in the United States. In Florida, since 1970, there have been a total of nine cases reported. No cases were reported in 1987 and one case was reported in 1988 in Indian River County.

Health Manpower

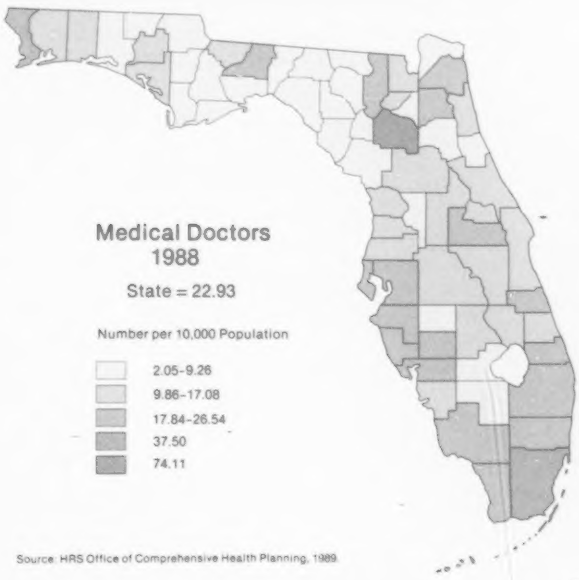
Physicians

Physicians include medical doctors, osteopaths, chiropractors and podiatrists. All physicians diagnose and treat human diseases and abnormal physical conditions, but each discipline uses a somewhat different approach.

Medical Doctors

Medical doctors practice allopathic medicine, which makes use of all measures proven effective in the treatment of disease. They are licensed under the provisions of Chapter 458, *Florida Statutes*, and licensing may be by examination, endorsement, temporary certificate for areas of critical need, or by a public health certificate to work at county public health units. Limited licenses are available for retired medical doctors who may then practice only in the employ of public agencies or non-profit agencies located in areas of critical medical need. Medical doctors must be graduated from an approved medical school and have completed one year of internship prior to examination for licensure.

The number of medical doctors per 10,000 ranges from 2.05 in Wakulla County to 74.11 in Alachua County. Glades, Sumter, Lafayette and Dixie also have a very low rate of physicians per 10,000 population. Therefore, each of these counties has been identified as a health manpower shortage area by the federal government. In addition to Alachua, other counties with a relatively high rate of physicians per 10,000 population include Sarasota, Duval, Hillsborough and Dade. However, Alachua County has 74.1 doctors per 10,000 population or 96.0 percent more physicians per 10,000 population than Dade County, which has the next highest rate at 37.5 per 10,000 population. Alachua County has a medical school, a Veteran's Administration hospital and a large teaching hospital, which accounts for the high physician to population ratio. Dade and Hillsborough Counties both have medical schools.



Medical Doctors
1988

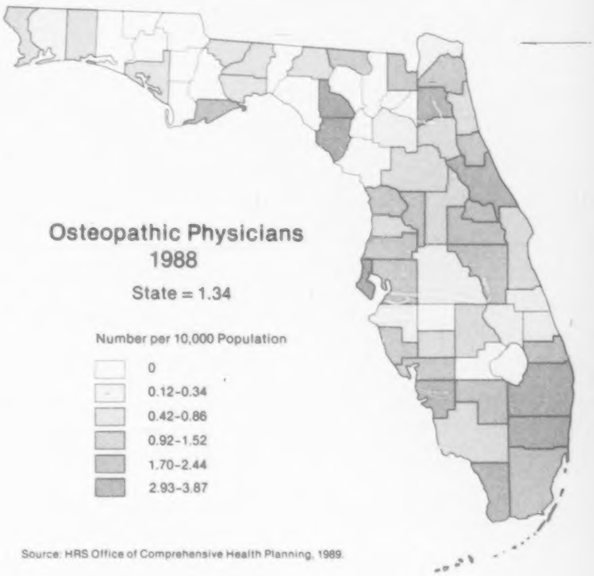
State = 22.93

Source: HRS Office of Comprehensive Health Planning, 1989.

Osteopathic Physicians

Osteopathic medicine is similar to allopathic medicine except that its practice emphasizes the importance of the musculoskeletal structure and manipulative therapy in the maintenance and restoration of health. Osteopaths are licensed under Chapter 459, *Florida Statutes*.

Seventeen Florida counties do not have an osteopathic physician. Polk, Alachua, Nassau, St. Lucie and Santa Rosa Counties have the fewest osteopaths per 10,000 population. Each report fewer than .3 osteopaths per 10,000 population. Franklin, Monroe, Dixie, Pinellas and Lafayette rank highest with each county having more than 2.0 osteopaths per 10,000 population. Lafayette County has 3.87 osteopaths per 10,000 population.



Osteopathic Physicians
1988

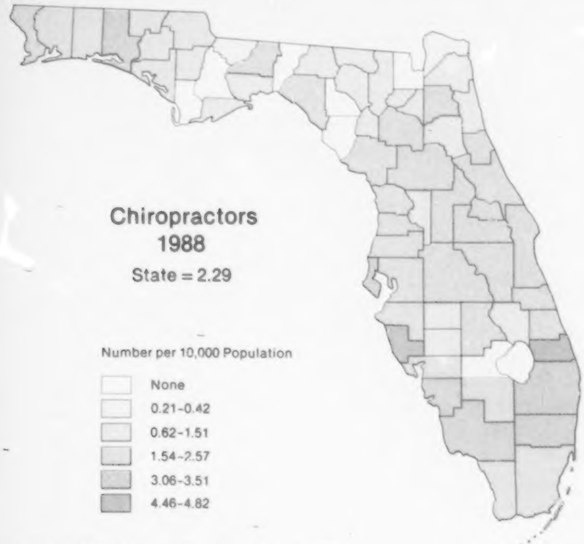
State = 1.34

Source: HRS Office of Comprehensive Health Planning, 1989.

Chiropractic Physicians

Spinal manipulation or adjustment is the usual and customary treatment procedure in chiropractic medicine. Chiropractic physicians primarily treat musculoskeletal disorders, but may treat organic or visceral disorders, based on the premise that correction of spinal defects may improve function in other areas because of the spine's dominant position in the nervous system. Chiropractors may use physical therapy and acupuncture, administer vitamins, render nutritional advice and administer proprietary drugs and injectable vitamins upon certification for each of these specific procedures. Chiropractors are licensed under Chapter 460, *Florida Statutes*. To be eligible for license examination, candidates must have a bachelor's degree and have earned a doctorate in chiropractic medicine from one of nine accredited colleges.

Seven counties do not have a chiropractor. The remaining counties have between .21 and 4.82 chiropractors per 10,000 population. Gadsden County has the lowest rate at .21 per 10,000 population, and Martin County has the highest rate. Seven of the ten counties reporting low chiropractic ratios are located in the Panhandle, while most of those with high ratios are along the coast in central and southern Florida.

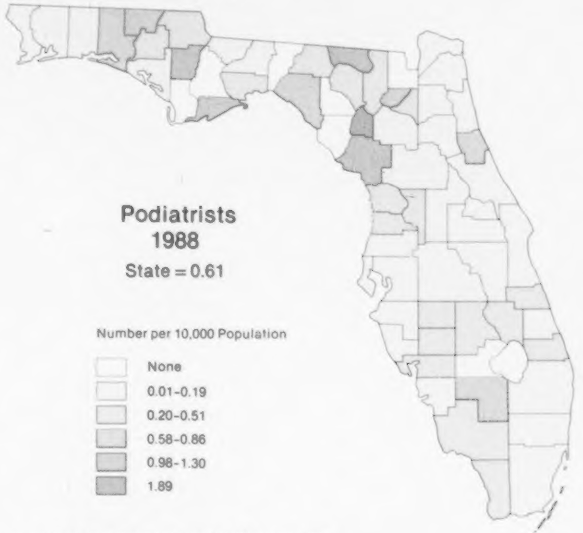


Source: HRS Office of Comprehensive Health Planning, 1989.

Podiatric Physicians

Podiatric physicians provide the diagnosis, treatment and prevention of abnormal conditions of the feet. Podiatrists perform surgical procedures on the foot, prescribe corrective devices, and prescribe and administer drugs and physical therapy. They deliver a wide range of services, including the medical and surgical treatment of corns; callouses; bunions; bursitis; flatfeet; disease of the skin and nails; and foot injuries affecting bones, tendons, muscles and joints. Podiatrists also serve as an entry point into the health care system for patients with systemic diseases which are manifested through symptoms in the feet. These patients are referred to other physicians for treatment of the underlying illness. Podiatric physicians are licensed under Chapter 461, *Florida Statutes*. In order to be licensed, candidates must have received their professional education at one of the colleges of podiatric medicine accredited by the Council on Podiatric Medical Association. Most students enter colleges of podiatric medicine after completion of a bachelor's degree. The podiatry curriculum involves four years of study, after which most graduates engage in podiatric residency training programs for one or more years.

Seven Florida counties are without a podiatrist. Of the ten counties reporting the lowest ratios, all have fewer than .05 podiatrists per 10,000 population. Dade County is the only county in Florida with a school of podiatry, and ironically, it has the lowest rate of podiatrists with .01 per 10,000 population. The greatest number of podiatrists per 10,000 population is in Gilchrist County with 1.89 per 10,000 population. Nine of the ten counties reporting high podiatrist ratios are located in northern Florida; Hendry County is the only exception.

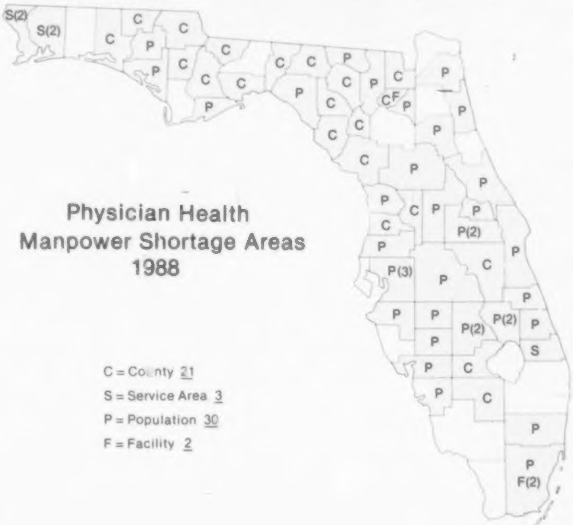


Source: HRS Office of Comprehensive Health Planning, 1989.

Physician Health Manpower Shortage Areas

In order to ameliorate the problem of physician shortages, health manpower shortage areas (HMSA) have been established by the federal government for primary care physicians. In Florida, 21 entire counties have been designated as primary care physician manpower shortage areas, three counties have service area shortages, 30 have shortages relative to specified subpopulations and two have facilities with shortages.

Areas are designated based on a formula which considers total population low income groups, poverty rates and the number of primary care physicians available to serve a defined population. In general, the desired ratio is one primary care physician per 3,500 persons. Once an area has been designated as an HMSA, it is eligible to receive a National Health Service Corps assignee.



Source: HRS Office of Comprehensive Health Planning, 1989.

An entire county can qualify by having too few physicians to meet the needs of its population. A specified geographic portion of a single county may have a physician shortage and may be designated as a service area or a county may have an identified subpopulation of medically needy persons such as Medicaid enrollees which is eligible for designation. Finally, a facility within a county, such as a prison or hospital, can become eligible based upon inadequate staffing.

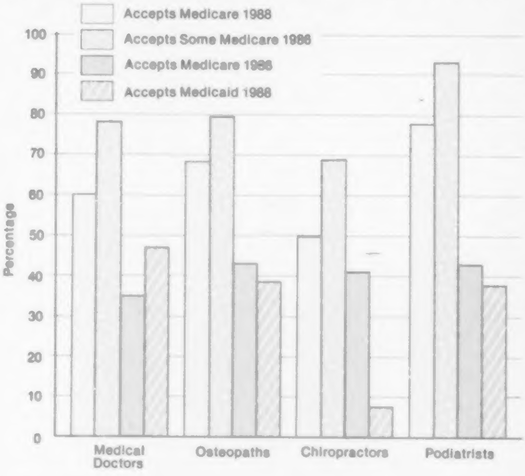
Medicare and Medicaid Participating Physicians

Mandatory biennial licensure renewal surveys of all licensed physicians have been conducted by HRS and the Department of Professional Regulation for several years in order to develop listings of practitioners who accept Medicare cost assignment. With at least one medical doctor in each county in Florida, the survey shows that Liberty County is the only county without a medical doctor who accepts Medicare. The counties with the highest percentage of medical doctors who accept Medicare cost assignment include Calhoun, Dixie, Gilchrist, Holmes, Lafayette and Wakulla. Each reported 100 percent acceptance. This may be because of the fact that these are relatively small counties with few medical doctors.

Statewide, podiatrists indicated the highest frequency of Medicare acceptance in 1988 with 76.9 percent. This is followed by osteopaths (67.8 percent); medical doctors (60.5 percent); and chiropractors (49.6 percent). The 1986 questionnaire also assessed partial participation in Medicare. The percentages of physicians accepting Medicare without exception is lower overall than reported in the 1988 survey. In 1986, podiatrists reported the highest rate of Medicare acceptance at 43.3 percent, followed by osteopaths (42.7 percent), chiropractors (40.7 percent), and medical doctors (34.8 percent). However, the percent of physicians accepting Medicare under certain circumstances is higher than in 1988. For example, podiatrists ranked highest among physician groups accepting Medicare some of the time at 93.0 percent. This is followed by osteopaths (79.0 percent), medical doctors (77.6 percent) and chiropractors (68.6 percent).

There are no comparative Medicaid data from the 1986 survey. Overall, the rate of Medicaid acceptance by all physician groups is lower than the rate of Medicare acceptance. Medical doctors indicate the highest rate of Medicaid acceptance (47.6 percent), followed by podiatrists (38.4 percent), osteopaths (37.9), and chiropractors (7.39). Further, over 50 percent of all Florida counties are without a chiropractor, podiatrist, or osteopath who accepts Medicaid.

Physicians Participating in Medicare and Medicaid



Source: HRS Office of Comprehensive Health Planning, 1989

The following table includes data from the 1988 physician survey, showing the percent of medical doctors, osteopaths, chiropractors and podiatrists accepting Medicare and Medicaid during 1988. The data reflect the percentage of doctors in each county participating in these programs, based on survey response.

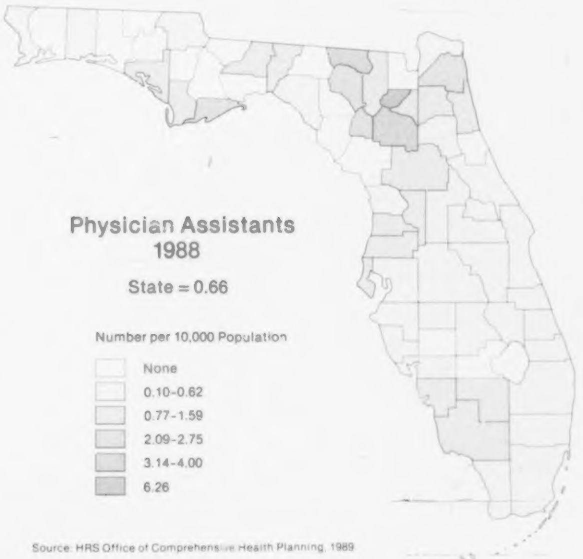
Physician Assistants

Physician assistants are certified under Chapter 458.347, *Florida Statutes*. Physician assistants have been educated and trained for the purpose of delivering high quality, cost effective health care under the supervision of a physician. Forty-eight states, including Florida, have enacted legislation governing the practice of physician assistants. Physician assistants enable medical doctors and osteopaths to delegate health care tasks when such delegation is consistent with a patient's health and welfare. The functions of a physician assistant include patient evaluation, monitoring, diagnosis, therapy, counseling, referral and preventive care. The University of Florida is the only school in the state currently offering a program. Students may begin the course of study ~~after 64 hours~~ of undergraduate preparation, although most have bachelor's degrees when they enroll. Graduates receive a bachelor's degree in Health Science at the end of two years.

There are very few physician assistants in Florida. Only 14 or 20.8 percent of Florida counties have more than one physician assistant per 10,000 population. Sixteen counties do not even have a physician assistant. Of those that do, Charlotte County has the fewest with .10 per 10,000 population. Additionally, seven of the counties surrounding Union County report high ratios due primarily to the physician assistant program at the University of Florida.



Physician Assistants

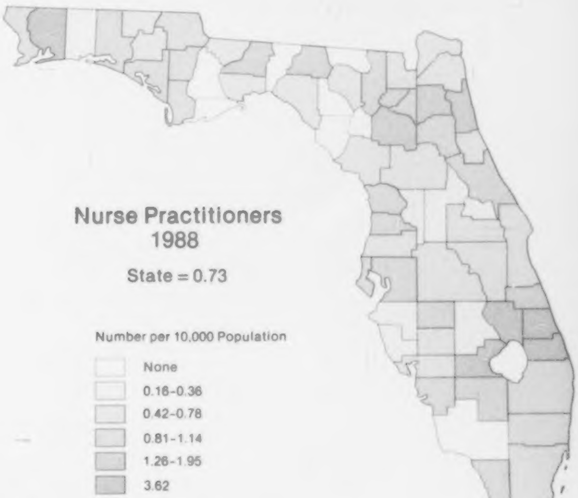
Nurses

There is a shortage of nurses in the United States today. According to the Department of Health and Human Services, 200,000 nurses are needed to fill current vacancies. In fact, three quarters of the nation's hospitals do not have enough nurses. The vacancy rate for nurses was 11.3 percent in 1987, up from 4.4 percent in 1983. However, nursing enrollment dropped 19 percent between 1983 and 1986, and the number of students admitted to undergraduate programs alone declined 30 percent for the same period.

The shortage may be attributed to numerous factors. Low salaries are often one of the primary deterrents. The 1987 average entry level salary in Florida was only $20,964. Since the implementation of the prospective payment system diagnostic related groups (DRGs) and resulting hospital staff reductions, nurses are often expected to do work previously done by aides, assistants, and other support staff. Nurses may work back-to-back shifts and have to care for more patients, usually those who require more extensive services. As a result, many nurses are leaving the profession and, at the same time, fewer are entering nursing schools.

Nurses are licensed under Chapter 464, *Florida Statutes*, and are of three classes: advanced registered nurse practitioners (ARNP), registered nurses (RN) and licensed practical nurses (LPN). Nurse practitioners are registered nurses with post-basic education training including one year of academic courses or a Master's degree or certification by a special board. They perform all the duties of a registered nurse and advanced level nursing approved by the Board of Nursing. Within the context of advanced or specialized nursing practice, a nurse practitioner may perform nursing diagnosis and nursing treatment of alterations of the health status. The advanced registered nurse practitioner may also perform acts of medical diagnosis and treatment, prescription and operation which are identified and approved by a professional committee.

Statewide, there are .73 ARNPs per 10,000 population. There are fewer ARNPs than any of the other nursing categories. In 1985, eight counties were without an ARNP, and 13 reported having only one ARNP. Palm Beach, Hillsborough, Pinellas, Broward and Dade Counties reported the greatest number of ARNPs. The number of ARNPs is greatest in the urban counties and lowest in the rural counties, primarily in northern Florida. Okeechobee, St. Johns, Madison, Alachua, and Santa Rosa Counties report the highest ratio of ARNPs, all with greater than 1.35 per 10,000 population. Sarasota, Manatee, Seminole, Highlands and Okaloosa Counties report the lowest rates, all less than .35 per 10,000 population.



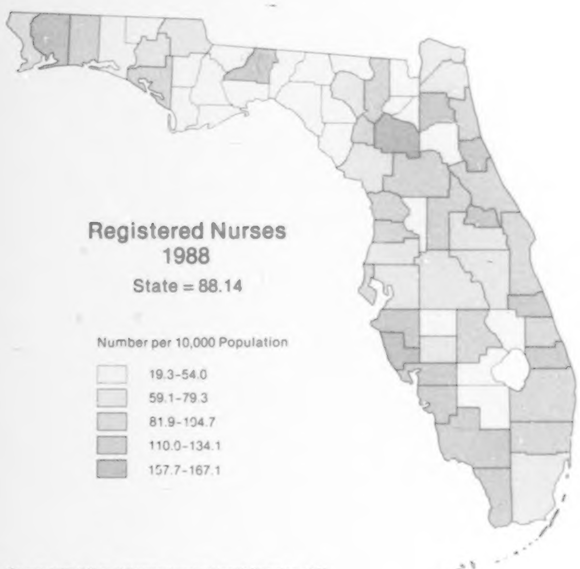
Nurse Practitioners
1988

State = 0.73

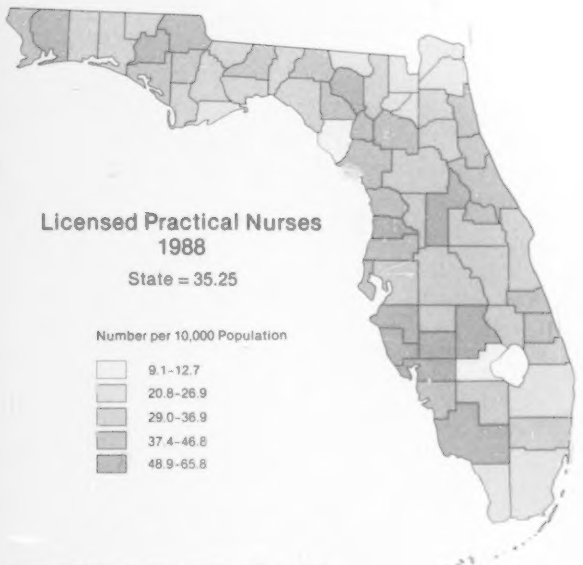
Source: HRS Office of Comprehensive Health Planning, 1989

Registered nurses (RNs) are expected to perform those acts requiring substantial specialized knowledge, judgement and nursing skill based upon applied principles of psychological, biological, physical and social sciences. They must pass an examination administered by the National Council for RNs.

The majority of counties reporting low RN ratios are rural counties in North Florida. Rural counties experience unique recruitment and retention problems because of the location of the facility, the inability of many rural health facilities to offer sophisticated equipment and learning opportunities and an inability to offer the most competitive salaries. The highest nurse-to-population ratios are found in counties near nursing colleges.



Source: HRS Office of Comprehensive Health Planning, 1989.



Source: HRS Office of Comprehensive Health Planning, 1989.

Licensed practical nurses (LPNs) are expected to perform services including the administration of treatments and medications in the care of the ill, injured or infirm and the maintenance of health and prevention of illness of others, under the direction of a registered nurse or a medical doctor, osteopath, podiatrist or dentist. LPNs can be licensed by examination or endorsement.

Only six of the ten counties reporting low LPN ratios are located in the Panhandle versus 80 percent of the RN counties. Five of the top ten counties reporting high LPN-to-population ratios have a LPN program in the county and two are contiguous to counties with programs.

Midwives

Certified nurse midwives are licensed registered nurses who have received advanced training at a university-affiliated nurse midwifery education program. Nurse midwives care for essentially low-risk women during pregnancy, labor and birth. They also care for the new-born baby and mother following birth. Nurse midwives always work in a team with physicians and other health professionals so that medical consultation or assistance is available should it be required. The University of Florida and the University of Miami each offer a master's level nurse midwifery educational program.

Lay midwives are licensed under Chapter 467, *Florida Statutes*. This law applies only to lay midwives with a valid license on October 1, 1984, or persons who were enrolled in one of Florida's two approved schools for lay midwives on that date. Lay midwives accept only clients who are low-risk and who have had a complete history, physical, and risk assessment by a physician. Lay midwives usually deliver babies in the client's home or at a birth center.

Optometrists

Optometrists are licensed under Chapter 463, *Florida Statutes*. The practice of optometry includes diagnosis of the human eye and its appendages; the determination of the refractive powers of the human eyes, or any visual, muscular, neurological or anatomic anomalies of the human eyes; and the prescribing and employment of lenses, contact lenses, and any other means or methods for the correction, remedy, or relief of any insufficiencies or abnormal conditions of the human eyes. Specially certified optometrists may administer or prescribe topical ocular pharmaceutical agents.

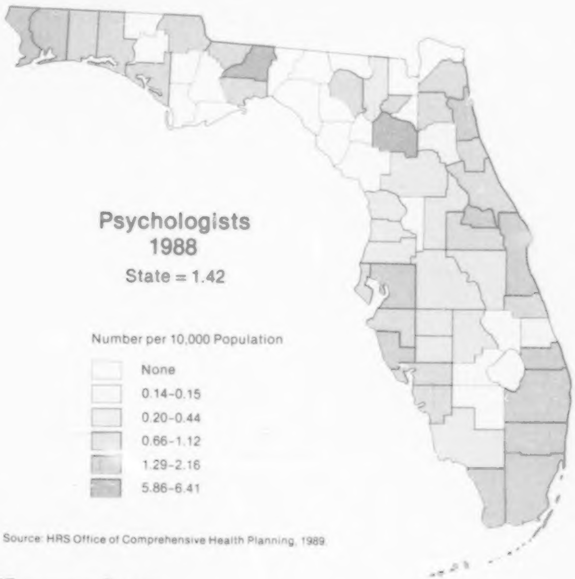
Pharmacists

Pharmacists are licensed under Chapter 465, *Florida Statutes*. The practice of pharmacy includes compounding; dispensing; and consultation concerning contents, therapeutic values, and uses of any medicinal drug. It also includes consultation concerning therapeutic values and interactions of over-the-counter preparations. Under the 1986 Florida self-care pharmacy regulation, pharmacists may consult with patients and dispense about thirty drugs previously available only by a physician's prescription. Florida A & M University and the University of Florida each offer a bachelor's degree and a doctorate in pharmacy.

Psychologists

Psychologists are licensed under Chapter 490, *Florida Statutes*. An applicant must have a doctorate in psychology from a program approved by the American Psychological Association and two years of full-time, supervised experience in the field of psychology.

There are 21 counties in Florida without a psychologist. St. Lucie County has the lowest rate with .14 psychologists per 10,000 population, followed by Putnam, Osceola, Pasco and Hernando counties, all with fewer than .22 psychologists per 10,000 population. Alachua County has the highest rate with 6.41 psychologists per 10,000 population. Other counties with high ratios include Leon, Hillsborough, and Dade Counties. Like Alachua, these counties have colleges with educational programs in psychology.



Source: HRS Office of Comprehensive Health Planning, 1989.

Therapists

Physical Therapists

Physical therapists are licensed under Chapter 486, *Florida Statutes*. Physical therapy includes treatment and prevention of disability, injury, or disease and related rehabilitation by the use of the physical, chemical and other properties of air, cold, heat, electricity, exercise and massage. Other agents which may be used in therapy are radiant energy, ultra sound, and water. Florida A & M University, Florida International University and the University of Florida offer bachelor's degrees in physical therapy. The typical student begins his course of study after completing 64 college credits at the undergraduate level. In addition, the University of Miami and the University of Florida each offer a master's degree program.

Occupational Therapists

Occupational therapists are licensed under Chapter 468.201, *Florida Statutes*. Occupational therapy is the evaluation and treatment of individuals whose ability to complete the tasks of living is threatened or impaired by developmental deficits, the aging process, poverty and cultural differences, physical injury or illness, or psychological and social disability. The treatment utilizes task-oriented activities to prevent or correct physical or emotional deficits or to minimize the disabling effect of these deficits in the life of the individual. Florida International University and the University of Florida offer degrees in occupational therapy.

Respiratory Therapists

Respiratory therapists are licensed under Chapter 468, *Florida Statutes*. They provide respiratory care services to patients with deficiencies and abnormalities associated with the cardiopulmonary system: use of medical gases, gas administration apparatus, humidification, environmental control systems and aerosols; respiratory rehabilitation; administration of drugs and medicines to the cardiopulmonary system; maintenance of natural and artificial airways; assistance with cardiopulmonary resuscitation; and specific testing techniques related to the cardiopulmonary system.

Clinical Laboratory Personnel

Clinical laboratory personnel licensed under Chapter 483, *Florida Statutes*, include four levels: (1) clinical laboratory director, (2) clinical laboratory supervisor, (3) medical technologist, and (4) medical technician. Medical technologists perform laboratory tests for the detection, diagnosis, and treatment of disease. These tests are performed in conjunction with pathologists and other physicians or scientists who specialize in clinic chemistry, microbiology or the other biological sciences. Medical technologists develop data on the blood, tissues, and fluid in the human body by using a variety of precision instruments. They perform complex analyses, fine line discrimination and correction of errors. Further, they are able to recognize interdependency of tests and have knowledge of physiological conditions affecting test results, so they may confirm their results and develop data which may be used by a physician in determining the presence, extent, and possible cause of disease. Medical technicians perform routine, uncomplicated procedures in the areas of hematology, serology, blood banking, urinalysis, microbiology and clinical chemistry.

Radiology Personnel

There are three types of radiologic personnel qualified to use X-rays on human beings under the specific direction of a licensed physician: basic x-ray technicians, general radiographers and nuclear medical technologists. They are certified by the Department of Health and Rehabilitative Services under Chapter 468, *Florida Statutes*. Basic X-ray technician training requires the least education with a high school diploma, certification and a state examination. Applicants for certification as a general radiographer or nuclear medicine technologist must have successfully completed a 24 month course of study in radiologic technology in a school approved by the Department of Health and Rehabilitative Services or completed a course of study provided by the Department. They are certified by the state and must complete a state examination as well as receive national endorsement.

Emergency Medical Personnel

Two types of emergency medical personnel are certified by the Department of Health and Rehabilitative Services under Chapter 401, *Florida Statutes*: emergency medical technicians (EMT) and paramedics. An EMT must be certified in cardiopulmonary resuscitation, complete an approved training course and pass a state proficiency examination. An EMT can perform first aid techniques considered to be non-invasive, such as the application of splints. A paramedic is required to have served at least a year as an EMT, completed a training course accredited by the American Medical Association, and passed a state proficiency examination. Under the supervision of a physician, a paramedic may use life saving techniques, such as intubation to administer drugs and intravenous fluids and cardiac defibrillation.

Dental Practitioners

Dentists and dental hygienists are licensed under Chapter 466, *Florida Statutes*. Dentists examine, diagnose, and treat conditions within the oral cavity and its adjacent tissues and structures. Acting under the supervision of a dentist, dental hygienists may remove calculus, perform root planing and curettage, expose X-rays and apply topical agents to teeth.

Only two Florida counties are without a dentist, Gilchrist and Glades. Union County has the lowest ratio of counties with dentists (.89 dentists per 10,000 population). Franklin, Hardee, Walton and Wakulla Counties, all have fewer than 1.5 dentists per 10,000 population. In 1988, Florida had 22 entire counties, five service areas, seven population groups and one facility designated as dental health manpower shortage areas, representing 33 Florida counties. Alachua has the highest dentist-to-population ratio (11.32 dentists per 10,000). Florida's dental college is located at the University of Florida in Alachua County.

Selected Demographic and Practice Characteristics of Florida's Health Professionals

Surveys of licensed health care professionals conducted over the past three years have yielded substantial data on the characteristics of Florida's health manpower. Since 1986, twelve professions have been surveyed: pharmacists, dentists, physician assistants, licensed practical nurses, registered nurses, nurse practitioners, psychologists, chiropractors, podiatrists, osteopaths, medical doctors, and clinical laboratory personnel.

Race and Sex

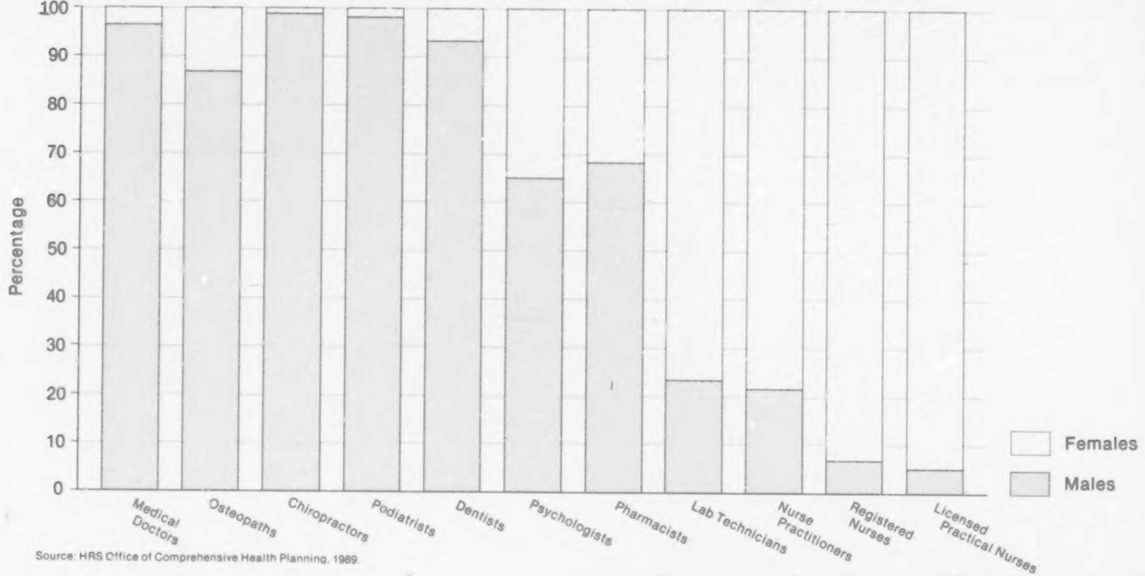
Cross tabulations of age and race data are available for the health care professionals surveyed in 1987 and 1988. The data concerning race are almost identical for all of the health care professions. Over 85 percent of all physicians are white males. Black males outnumber white females in each physician group. Black females represent less than 0.5 percent of all physician groups in the state of Florida.

Psychologists are slightly more diverse, with 64 percent white males and 33 percent white females. However, less than five percent of all Florida psychologists are minorities.

The nursing professions are primarily female and, again, primarily white. The LPN profile includes 95.3 percent female and approximately 15 percent minorities. Over 90 percent of RNs are white females. There is a greater percentage of male ARNPs (23.7 percent) than in the other nursing classifications.

Clinical laboratory personnel have a somewhat different profile. Approximately 70 percent are females and 86.9 percent are white. The nursing and laboratory professions are dominated by women, and the physician and psychology fields are male-dominated professions. Universally, each group is primarily white with few minorities represented in these health care professions.

Distribution of Selected Florida Health Care Professionals by Sex, 1988



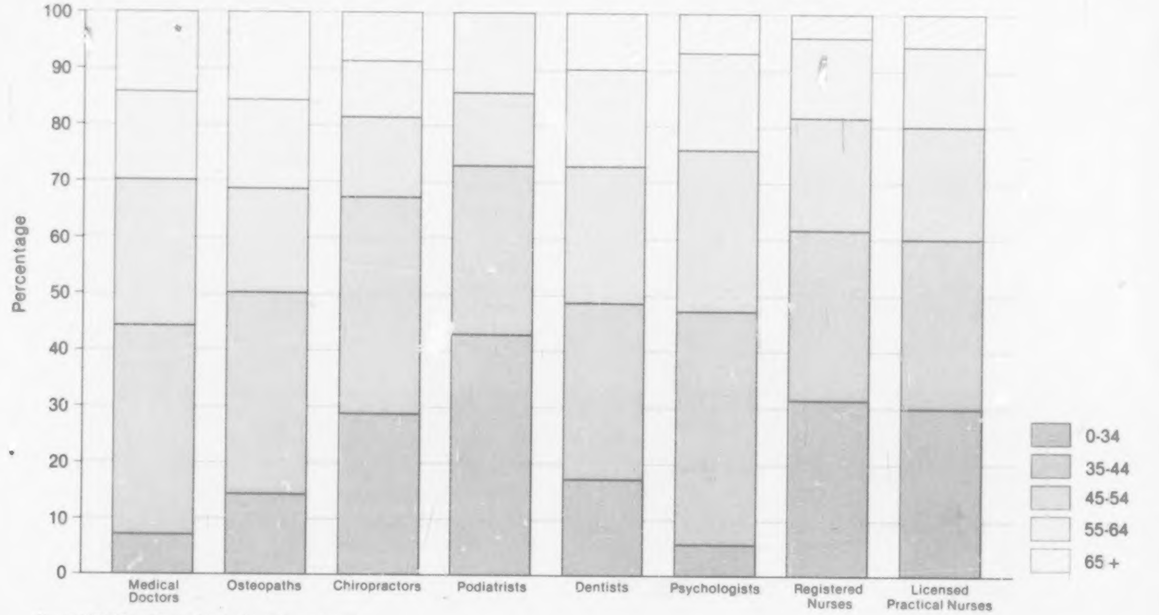
Source: HRS Office of Comprehensive Health Planning, 1989.

Age

Age cohort data suggest that the majority of dentists, psychologists, medical doctors, chiropractors, podiatrists and osteopaths are between the ages of 35 and 54. Osteopathy reflects the largest percentage of professionals over the age of 65 at 12.9 percent. Podiatrists, as a physician group, have the greatest percent of professionals under the age of 34 at 44.1 percent of all professionals reporting. Dentists, medical doctors, osteopaths and psychologists all tend to be slightly older than the chiropractors and podiatrists. There is also a large number of chiropractors under the age of 34, 29.4 percent of all respondents. Age cohort data for RNs indicates that 62.1 percent of RNs are under 44 years of age. Age cohort data for LPNs reveals that over 60.0 percent of LPNs are under the age of 45. The graph presents age cohort data, where available, for each of the professional groups. The graph specifies the percent of professionals in each age category.

The mean age is available for the nursing and laboratory professions. Nurse practitioners report the highest mean age at 42.6, and LPNs and RNs are the same at 42.2 years old. The laboratory personnel mean ages range between 51.6 for directors and 37.4 for technologists. Laboratory supervisors have a mean age of 43.1 and technicians have a mean age of 39.5.

Distribution of Selected Florida Health Care Professionals by Age Group, 1988



Source: HRS Office of Comprehensive Health Planning, 1989.

Primary Practice Setting

Physicians, psychologists, and physician assistants generally work in a private setting. Podiatrists rank highest with 89.0 percent reporting private practice as their primary setting. Registered nurses most often work in a hospital setting as do licensed practical nurses. Psychologists report the highest rate of employment in an academic setting. The nurse practitioners report the highest rate of government employment. Clinical laboratory personnel are most frequently employed in a hospital setting.

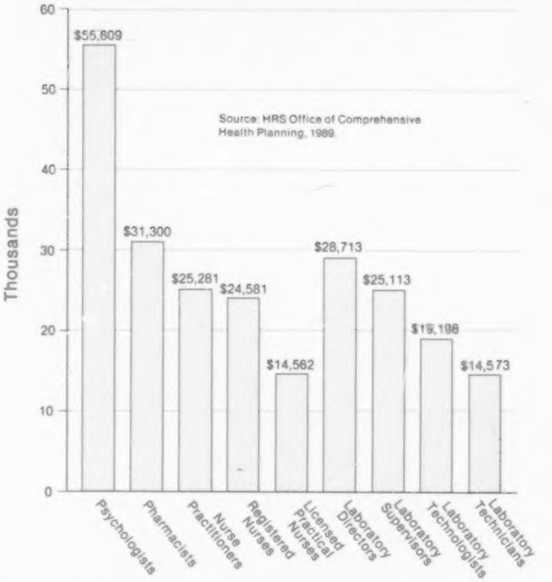
The percentage of each professional group working in a given practice setting is specified below. The practice locations include private practitioners' offices, hospitals, educational facilities, nursing homes, government facilities (military, Veteran's Administration), outpatient/ambulatory care clinics and other settings. There is an increasing trend in outpatient clinic employment because of the overall shift in the delivery of health care services to an outpatient basis. The other category includes such settings as industry, research agencies and home care.

Comparative practice setting data from 1986 suggests a similar practice profile for the physician group. The rate of private practice employment is almost identical for 1986 with the exception of the decline in private practice for podiatrists. In 1986, 98.5 percent of all podiatrists declared private offices as their primary practice setting. In contrast, national data suggest an overall increase in the percent of psychologists opening private practices.

Salary

Florida average salary data is available for some professions. Of those professions providing income data, psychologists report the highest average salary, $55,609, followed by pharmacists, $31,300. Nurse practitioners report the highest average salary among nursing personnel, $25,281, followed by registered nurses, at $24,581, an average salary of 2.8 percent less than nurse practitioners.

Average Annual Salaries for Selected Florida Health Care Professionals, 1988



Source: HRS Office of Comprehensive Health Planning, 1989.

LPNs report an average annual salary of $14,562. Clinical laboratory directors report the highest average salary among laboratory personnel at $28,713, supervisors earn $25,113, technologists earn $19,198 and technicians earn on average $14,573 annually.

Licensed Practitioners by County

The tables on the following pages display the number of licensed practitioners in each manpower category for each Florida county. In most cases, the tables include all persons with active licenses registered with the Department of Professional Regulation, not just those that are actively practicing. For registered nurses, licensed practical nurses and nurse practitioners, the tables reflect actively practicing nurses.

Percent Distribution of Selected Florida Health Care Professionals by Practice Location, 1988

Profession	Primary Practice Location						
	Private Office	Hospital	Nursing Home	Educational Facility	Government Agency	Outpatient Clinic	Other Setting

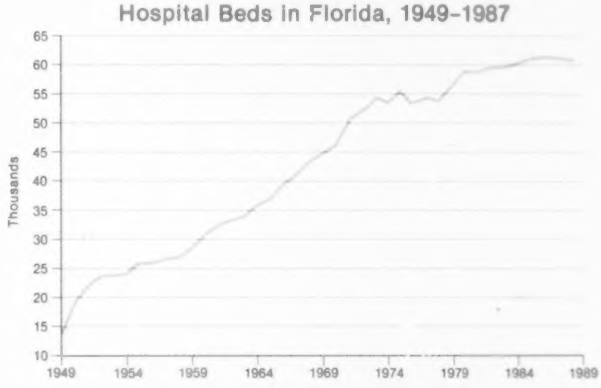
Health Facilities Utilization

Hospital Utilization

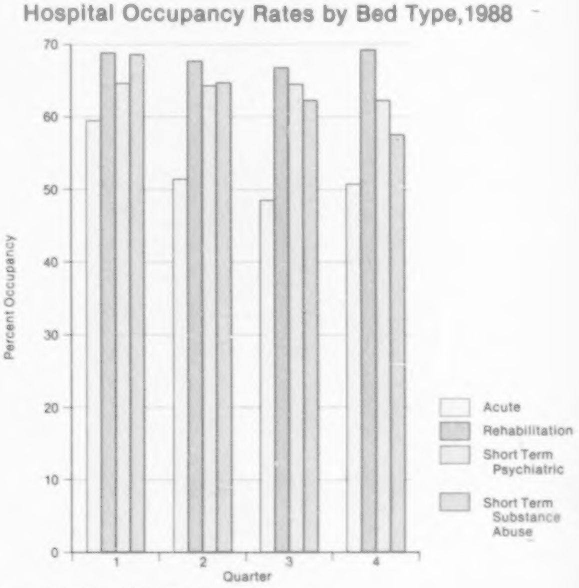
In Florida, the number of hospitals increased from 119 facilities with 14,091 beds in 1949 to 309 licensed specialty and acute care hospitals with 61,060 beds in mid 1989. Florida has continued to experience an increase in the number of hospitals as the national hospital bed supply has declined. Between 1977 and 1987, Florida experienced a 12 percent increase in the number of hospitals and hospital beds while the nation closed 278 hospitals and 140,000 beds. This history of strong hospital growth is partially due to the large percentage of population over 65 years of age, rapid population growth, and strong economic growth.

The statewide acute care hospital occupancy rate in 1988 was 52.4 percent. The statewide occupancy rates for short term psychiatric and short-term substance abuse beds were slightly higher at 63.5 percent and 61.6 percent. Florida's acute care bed utilization has dropped significantly since 1984 as a result of the implementation of the Medicare Diagnosis-Related Group (DRG) reimbursement system and other factors such as modifications in medical practice, increased utilization controls, increased competition, and managed care contracting. As a result, the number of specialty hospital beds is increasing. In 1989, there were 4464 short term psychiatric, 1063 short term substance abuse, and 1300 rehabilitation beds in Florida's general and specialty hospitals.



Source: Hospitals, 1949-1971, Hospital Statistics, 1972-1987, American Hospital Association.

Historically, Florida experienced a trend of rapid hospital bed growth as well as a growth in admissions from 1949 to 1959, with a 96 percent increase in beds and over a 100 percent increase in admissions. From 1969 to 1979, hospital beds increased 25 percent and admissions increased [illegible]2 percent. Since 1979, growth has slowed significantly with bed increases of only eight percent and an actual decline in admissions.



Source: HRS Office of Comprehensive Health Planning, 1989.

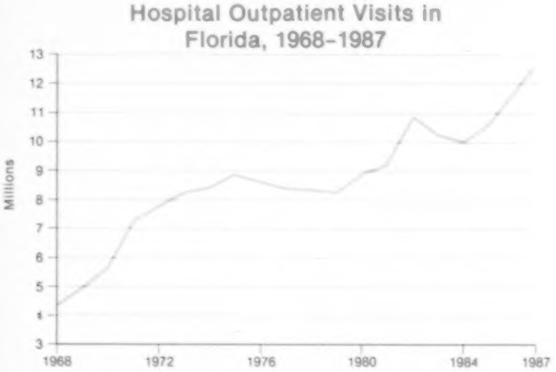
Source: Hospitals, 1949-1971, Hospital Statistics, 1972-1987, American Hospital Association.

While hospital admissions have declined in recent years, there was a 67 percent increase in outpatient visits between 1969 and 1979 and a 52 percent increase from 1979 to 1987. Outpatient visits per 1000 population increased by 11.7 percent between 1977 and 1987 nationally, and by 23.1 percent for the same period in Florida. While the number of outpatient visits per hospital in Florida increased by 53.1 percent between 1977 and 1987, total outpatient visits for 1987 remained below the national average of 43,758. The growth in outpatient visits is one reason for Florida's drop in hospital occupancy and indicative of recent de-emphasis on inpatient services for many routine procedures.



Source: Hospital Statistics, 1968-1987, American Hospital Association.

Even with declining occupancy and an increase in the number of ambulatory surgical procedures performed at other facilities, the number of surgical procedures performed in hospitals has increased from under 5 million operations in 1968 to over 12 million in 1987. From 1974 to 1987, the number of surgical procedures per year increased by 64 percent.

Open heart surgery and cardiac catheterization are two areas in which hospital utilization has increased substantially in recent years. As occupancy rates have declined, facilities have expanded their services in order to increase revenues. There are 45 acute care hospitals in Florida which perform open heart surgery and 12 additional facilities with certificate of need (CON) approval that are not yet operational. There are 63 hospitals and 24 CON approved facilities performing cardiac catheterizations.

In 1988, the largest number of open heart surgeries were performed in District 6, where five hospitals performing open heart surgery are located. District 7, with eight hospitals participating in cardiac catheterization programs, performed a total of 14,865 cardiac catheterizations or 16 percent of the 87,958 procedures performed statewide.

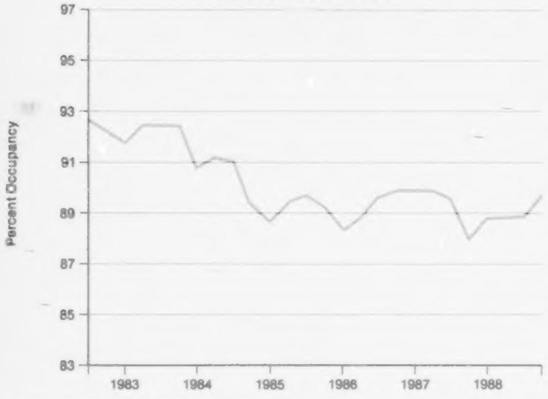
Nursing Home Utilization

Florida's population over age 65 will increase by 18 percent from 2,401,166 in 1989 to 2,844,227 in 1994. This projected increase in the elderly population represents 19.7 percent of Florida's total population. In comparison, only 13 percent of the projected United States population will be over 65 in 1994. The rapid growth of the elderly population has created increased demands for long term care. In 1989, Florida had 542 nursing homes with 61,447 licensed beds with an additional 12,457 beds under construction.

Florida's nursing home occupancy has shown a slight decline over the past six years. Overall state occupancy for nursing homes dropped gradually from a high of 92 percent in 1982 to 89 percent in 1988. High occupancy rates are expected to continue as the industry attempts to meet the growing demands of Florida's elderly population. Nursing home Medicaid occupancy as a percentage of available bed days has increased over the past six years from approximately 49 percent in 1983 to approximately 54 percent in 1988. Medicaid occupancy as a percentage of actual patient days was 60 percent in 1988.

Nursing Home Occupancy Rates, 1982-1988



Source: HRS Office of Comprehensive Health Planning, 1989.

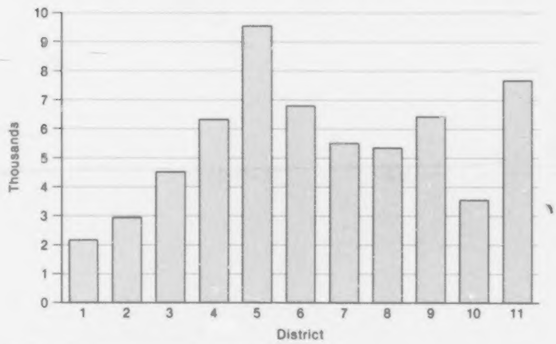
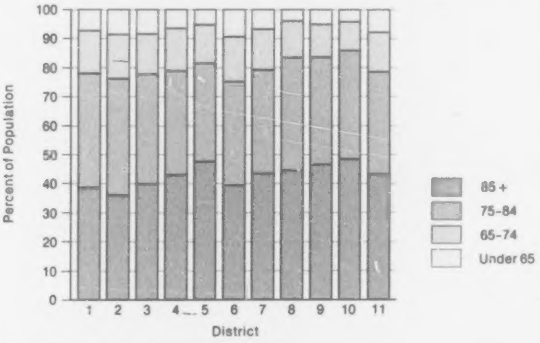
Licensed Nursing Home Beds by District, 1988



Source: HRS Office of Comprehensive Health Planning, 1989.

A 1986 Healthcare Cost Containment Board (HCCB) census of nursing homes by district indicated that 43.7 percent of the nursing home population is age 85 or older while 7.1 percent is under 65. HCCB's 1985 survey indicated that the proportion of patients 85 and over was 40.4. Analysis of the nursing home population in three age groups(65-74, 75-84, and 85 and over) showed that the greatest utilization is experienced by the 85 and over age group. This age group is also the fastest growing segment of the elderly population in Florida and the United States. Florida experiences, on average, a 4.3 percent increase in the population age 75 and older each year. An analysis of the elderly population by district indicates that Districts 3, 7, 8 and 9 have the highest annual percentage increase in this population group.

Attained Age of Nursing Home Patients Resident on December 31, 1987



Source: Health Care Cost Containment Board, 1989.

Many factors other than the size of the elderly population and the nursing home bed supply affect the utilization of nursing home and other long term care services. Policy changes which stimulate increased demands for long term care include the Medicare prospective payment system for hospitals which encourages patient discharge as soon as medically possible. The results of early discharge are manifested in increased demand for nursing home services for patients requiring sub-acute or convalescent care rather than being left to convalesce in hospitals. Socioeconomic considerations and personal circumstances also influence the level and type of long term care desired and provided in communities.

Home Health Services Utilization

Home health services have been available to Florida residents for several years through county health units, Visiting Nurse Associations (VNAs) and privately operated non-profit home health agencies. Nationally, for-profit agencies increased in the early 1980s because of Medicare reimbursement legislation. Prior to the passage of the Omnibus Reconciliation Act of 1980, for-profit agencies could not obtain certification in states not having a home health agency licensure law. Florida has regulated licensing of for-profit Medicare certified home health agencies since 1976. Nationally, as well as on the state level, Medicare certified home health agencies are increasing as for-profit sector investment increases.

The ten most populous states in the nation provided approximately 55 percent of the total Medicare home health visits in 1986. Eight percent of all visits for home health agencies in the United States were provided by Florida agencies. Florida ranks second only to Pennsylvania which provided 10 percent of the nation's total home health care. The extensive use of home health agencies in Florida is indicative of the number of elderly residing in the state.

Data on number of visits and persons served for the South Atlantic states show that in 1986, Florida home health agencies cared for 47.3 percent of all persons served and provided 53 percent of all visits. The average number of home health agency visits in the South Atlantic states in 1986 was slightly over 800,000. Florida agencies provided over 3.1 million visits in 1986.

Detailed data by age cohort is unavailable at this time. However, one district in Florida reported that, in 1987, the age breakdown of the total patient case load of those using home health agency services included the following: one percent were under the age of 31; 12 percent were ages 31-64; 34 percent were ages 65-74; and 53 percent were ages 75 and over.

Health Facilities Inventory

Florida has over 4,000 licensed health facilities and health services agencies ranging from small adult congregate living facilities with under three beds to large referral hospitals with over 1000 beds. Additional health care facilities such as ambulatory care centers or walk-in medical clinics are unlicensed by the state. Health care providers can generally be classified as medical treatment facilities, long term care facilities, mental health providers and diagnostic and support facilities. The following pages provide summary descriptions of the types of facilities, the number of facilities located in each district and county and their capacity.

Medical Treatment Facilities

Medical treatment facilities provide diagnosis and treatment of individuals with both acute and chronic conditions. Acute care services are provided for treatment of episodic injuries or illnesses with an average duration of less than 30 days, although recovery periods may be longer. Facilities may provide treatment on either an inpatient or outpatient basis. In many cases, patients are treated at the facility and allowed to return home the same day. Long term inpatient care is generally the exception.

Medical Treatment Facilities

Facility Type	Services	Legal Basis
Abortion Clinics	Perform abortions before the third trimester and provide counselling services to patients.	Chapter 390, Florida Statutes
Ambulatory Care Centers	Provide prompt evaluation and treatment of common health care problems to individuals who walk in to the facilities. Minor illnesses and injuries are treated on site while severe cases are referred to hospitals or other specialists after stabilization.	
Ambulatory Surgical Centers	Perform many gynecologic, urologic, orthopedic, and other minor surgical procedures on an outpatient basis.	Chapter 395, Florida Statutes
Birthing Centers	Provide an alternative to hospital delivery for low-risk pregnant women and their families who wish to experience natural childbirth in a home-like setting. They offer prenatal and postnatal care, labor and delivery services and counselling provided by nurse midwives, nurse practitioners, and registered nurses under the supervision of a family practice physician with consultation from an obstetrician.	Chapter 383, Florida Statutes
HRS County Public Health Units	Provide a basic program of public health services including protection of the public from environmental hazards, control of infectious diseases, health screening and evaluation services for early detection of disease, health education and counselling services, and diagnosis and treatment when necessary.	Chapter 154, Florida Statutes
Dialysis Centers	Provide maintenance dialysis and training in home dialysis to individuals suffering from end stage renal disease (kidney failure) who must undergo hemodialysis or peritoneal dialysis. Some centers also provide back-up dialysis and dialysis supplies to patients using continuous ambulatory peritoneal dialysis (CAPD) or continuous cycling peritoneal dialysis (CCPD).	
Health Maintenance Organizations (HMO)	Provide comprehensive medical services either directly or through contract arrangements to enrolled members for a fixed annual capitation fee: preventative health care, ambulatory diagnostic and treatment services, inpatient hospital care, inpatient and outpatient physician services, and emergency care. To become federally qualified, HMOs must also provide short-term-mental health services, medical treatment and referral services for drug abuse, and home health services. HMOs may provide pharmacies, dental offices, and optometric services.	Chapter 641, Part II, Florida Statutes
Hospitals	Provide a broad range of health care services to both inpatients and outpatients. General acute care hospital services include medical and surgical services, obstetrics, pediatrics, intensive care, and emergency treatment. Psychiatric services include both long and short term treatment for mental health and substance abuse problems. Comprehensive medical rehabilitation services include intensive care and therapy to rehabilitate patients with severe physical disabilities. Hospitals may also offer a variety of other services including blood banks, dialysis treatment, home health services, long term nursing care, outpatient surgery, birthing centers, health education, and risk prevention programs.	Chapter 395, Florida Statutes
Primary Health Care Centers	Provide the medically indigent with a wide range of ambulatory health care services including medical diagnosis and treatment, dental care, psychiatric counselling, and substance abuse treatment.

Long Term Care Facilities

Long term care facilities provide specialized health, social and residential services to individuals who require continual assistance as a result of chronic physical or mental impairments and others undergoing an extended recuperation from a major illness or injury. Among the persons commonly served by long term care facilities are individuals over age 65, patients with developmental disabilities and the terminally ill.

Long Term Care Facilities

Facility Type	Description	Legal Basis
Adult Congregate Living Facilities	Provide 24-hour personal care services to the impaired elderly and disabled low-income individuals who are eligible for Supplemental Security Income and Optional State Supplementation payments. Services may include assistance with bathing, eating, personal hygiene, housekeeping and ambulation as well as personal supervision, emotional security, supervision of self-administered drugs, and assistance in obtaining health care services. The facilities may also provide limited nursing services when specifically licensed to do so.	Chapter 400, Part II, Florida Statutes
Adult Day Care Centers	Provide a protective setting, social and leisure activities, nutritional services, and self-care training to elderly or impaired individuals who need services on less than a full-time basis. Some centers may also provide speech and physical therapy services or health services such as assessment, counselling, treatment, and referrals.	Chapter 400, Part IV, Florida Statutes
Adult Foster Homes	Provide supervised home living environments as an alternative to institutionalization or to assist those returning from an institutional setting. They provide similar services to the same client groups as ACLFs, but cannot exceed a capacity of three.	Chapter 10A-14, Florida Administrative Code
Home Health Agencies	Provide a broad range of services to patients in the home who are in need of intermittent care including skilled nursing, occupational speech and physical therapy, meals, homemaker services, respiratory therapy and intravenous therapy. Home health care services are usually provided by a visiting nurse or aide and care is administered through the supervision of a physician.	Chapter 400, Part III, Florida Statutes
Homes for Special Services	Provide specialized health care services, including personal and custodial care, but do not provide continuous nursing services to residents.	Chapter 400, Part II, Florida Statutes
Hospices	Provide an alternative to inpatient hospitalization for terminally ill patients and their families. They provide a continuum of home, outpatient and homelike inpatient care designed to meet the special needs of the dying. Services include the control of pain, nausea, vomiting, and other symptoms as effectively as medically possible; emotional and spiritual support for the family; and follow-up services to the family during bereavement.	Chapter 400, Part V, Florida Statutes
Intermediate Care Facilities for the Mentally Retarded (ICF/MR)	Provide an alternative to institutionalization for severely or profoundly retarded patients and retarded individuals with multiple handicaps who are eligible for Medicaid. They furnish a homelike residential setting that provides the atmosphere, training, and support necessary to stimulate behavioral change and allow the individual to function at the greatest possible level of independence. ICF/MRs provide room and board; medical, pharmacy, nursing, nutritional and dental services; direct care supervision; and training in self care, daily living, and socialization. Additional services may include physical, occupational, speech and music therapy, and social work services.	Chapter 393, Florida Statutes
Nursing Homes	Provide residential health and medical care services to patients requiring nursing care including the following minimum services: 24-hour nursing care, personal care or custodial care as needed; both routine and emergency physical services; and access to dental, other health-related, recreational, rehabilitative, and social work services. Nursing homes are also required to assist residents in obtaining other services if they do not provide them directly: pharmacy; laboratory; X-ray; dental, hearing, and vision care; diet, occupational, physical and speech therapy; mental health counselling, social services; and medical services.	Chapter 400, Part I, Florida Statutes

Source: HRS Office of Comprehensive Health Planning, 1989.

Mental Health Facilities

Florida provides a coordinated system of mental health services which serve as an alternative to long term institutionalization of the mentally ill. These facilities provide inpatient and outpatient screening, treatment, counseling, consultation and education to individuals with mental disorders and substance abuse problems.

Diagnostic and Support Facilities

Other facilities provide specific services which cannot easily be categorized as medical treatment, long term care or mental health services. These facilities may provide diagnostic or other testing services or supply medical equipment or supplies needed for the patient.

Mental Health Facilities

Facility Type	Description	Legal Basis
Adult Residential Treatment Systems (ARTS)	Serve individuals 18-54 who have either been discharged from or are at risk of being admitted to a state mental health treatment facility. The residential treatment facilities provide a continuum of staff supervision, support and assistance according to each client's level of self-sufficiency. The intensive day program provides personal, social, and vocational skills training to participants.	Chapter 394, Part IV, Florida Statutes
Community Mental Health Facilities	Provide programs designed to prevent mental illness and to diagnose, treat, and support individuals suffering from these conditions. Services include diagnosis, evaluation, prevention programs, outpatient treatment, day treatment, crisis stabilization, counselling, hospital inpatient diagnosis and treatment, and residential treatment.	
Crisis Stabilization Units (CSU)	Provide an alternative to inpatient hospitalization for mentally ill individuals who are in an acutely disturbed state. The facilities provide screening, assessment, medication and other appropriate services 24 hours a day, 7 days a week in order to stabilize patients and redirect them to the most appropriate setting available for further treatment.	Chapter 394, Part IV, Florida Statutes
Geriatric Residential Treatment Systems (GRTS)	Serve persons 55 or over who are afflicted with a chronic mental illness who have either been discharged from or are at risk of being admitted to a state mental health treatment facility. The residential components are licensed mental health treatment facilities which provide a continuum of medical services and treatment, staff supervision, support, and assistance according to each resident's physical, mental, and social capabilities. The intensive day program provides psychological treatment services and both personal and social skills training.	Chapter 394, Part IV, Florida Statutes
Psychiatric Hospitals	Provide both long and short term inpatient treatment for mental health and substance abuse problems.	Chapter 395, Florida Statutes
Substance Abuse Treatment Facilities	Provide either residential or outpatient diagnostic and treatment services to individuals suffering from a chemical dependency such as alcoholism or drug addiction. Substance abuse services include detoxification, individual and group therapy, and counselling and education services.	Chapter 397, Florida Statutes

Source: HRS Office of Comprehensive Health Planning, 1989.

Diagnostic and Support Facilities

Facility Type	Description	Legal Basis
Blood Banks	Collect, process and store blood and blood products for use in emergencies and natural disasters, surgical operations, blood replacement in accidents and treatment of individuals with conditions requiring blood transfusions.	Chapter 483, Part I, Florida Statutes
Clinical Laboratories	Perform examinations on materials and specimens taken from the human body to provide information needed for use in the diagnosis, prevention or treatment of disease, or the assessment of a medical condition.	Chapter 483, Part I, Florida Statutes
Diagnostic Centers	Provide specialized diagnostic and sophisticated radiological services such as computed tomography scans and magnetic resonance imaging on an outpatient basis.	
Multiphasic Health Testing Centers	Take specimens from patients for delivery to clinical laboratories and provide basic health testing such as electrocardiograms, audio and visual tests, and blood pressure determinations.	Chapter 483, Part II, Florida Statutes
Pharmacies	Provide drugs and pharmaceuticals to individuals.	Chapter 465, Florida Statutes

Health Facilities Listing

The following pages contain listings of health facilities arranged in alphabetical order by facility type. These listings represent the most recent data available to the Office of Comprehensive Health Planning at the time the lists were prepared. Facilities lists used to update this listing were obtained from many sources and in some cases complete addresses were not available. In other instances, facilities may have opened, closed or changed names since these lists were compiled. Any corrections should be reported to the Data Analysis Unit, Office of Regulation and Health Facilities, 2727 Mahan Drive, Tallahassee, Florida 32308, telephone 904-488-8394.
